

**EXHIBIT 2**  
**DESCRIPTION OF THE EXPERIMENT 2**

Rearden LLC seeks to conduct product development and market demonstration in the 3.5GHz range (using multiple 5MHz blocks for total of 50MHz between 3400-3550MHz and 3650-3700MHz) that will examine a new digital modulation technique for wireless networks, thereby providing important information for the development of next generation wireless communications applications for the business and consumer markets. Specifically, Rearden will install prototype base stations enabled with proprietary pCell™ wireless technology inside the SAP Center at San Jose that allows each wireless user inside the stadium to use the full data rate of shared spectrum simultaneously with all other users, by eliminating interference between users sharing the same spectrum. Rearden will examine network performance, features, and functionality of pCell wireless technology and a suite of customer applications. Testing is required to determine the viability of pCell wireless technology and its ability to support a variety of applications with a high density of concurrent users. In addition, testing is necessary to verify design characteristics and performance in an indoor environment with trial users, as well as other technical parameters.

Testing will consist of short-range transmissions inside the SAP Center at San Jose using indoor mounted base station antennas, which have been designed to operate at 3400-3550MHz and 3650-3700MHz, and commercial LTE user devices designed to operate at 3400-3550MHz or 3650-3700MHz. Transmit power of the base stations will be at most 100mW with 3W ERP and out-of-band emissions will meet 47 C.F.R. Part 27 limits. The base stations will be at fixed indoor locations and mounted indoor on the ceiling of SAP Center at elevation up to 100 feet AGL with antennas pointing downward. Given the limited transmit power, downward orientation of the antennas, installation of the base stations restricted to indoor locations and high pathloss of radio waves propagating at 3.5GHz through the concrete and steel structure of the SAP center, Rearden expects poor indoor-to-outdoor propagation with limited or unmeasurable RF energy being radiated outside the perimeter of the SAP center.

Some of the system variables to be tested include: range, capacity and customer application preferences. Rearden will conduct testing exclusively inside the SAP Center in San Jose, California. Access and use of the test network, platform, and applications will be limited to employees or full-time contractors of Rearden.

The proposed wireless communications experiment and the associated evaluation and/or customization of the above-referenced technology will advance the Commission's spectrum policies to promote innovation, and competition. The proposed experiments and trials have the potential to lead to more efficient and productive utilization of spectrum made available by the Commission for licensed and unlicensed operations.
