Description of experiment: EF Johnson has sets up base stations in various frequency bands for the purposes of testing EF Johnson product. The stations include conventional and trunked operation. The experiment involves using mobile and portable radios in an on-the-air situation to test various aspects of the product. This includes testing of radio hardware and software. Tests involve testing of radio operation in various propagation situations, including strong and weak signal conditions. Software protocol testing is also done including trunking protocol testing. The goal is to isolate radio performance issues, and to make improvements in radio product operation.
