FLIGHT LINE – STALL 1
IDENTIFIERS: 614T1

The following calculations are for System 14 transmit identifier 614T1. Calculations are based upon an average receive power for L1 of -130 dBm at the unit under test at the roof-mounted receive antenna. Transmit antenna, inside the building, is permanently installed pointing downward. The maximum antenna gain is 4.7 dBi at the focal point and is reduced at off-axis angles. The GLI-Metro signal level controller input range is -85 to -115 dBm. The range of output power level adjustment is -85 to -65dBm.

The attenuation of the GPS signal while traveling through free space is calculated with the following formula:

$$FSL = K1 + 20 \cdot \text{LOG}(D) + 20 \cdot \text{LOG}(F)$$

Where:

K1 = the constant factor (-37.87) for the desired units (feet),

F = the frequency in MHz; and

D = the slant range distance from the transmitter antenna to 100 feet beyond the nearest exterior wall in feet (152.2')

D₀ = Distance to the nearest outside wall (40 feet).

Slant Angle = The angle, based on the slant range, used to calculate the reduced antenna gain directed 100' beyond the nearest exterior wall.

We are calculating the GPS Re-radiation at 1575.42 MHz for L1.

Therefore, the Free Space Path Loss (FSL) for the horizontal distance from the antenna to the nearest exterior wall plus 100' equals:

1. For L1: $FSL = -37.87 + 20 \cdot \text{LOG}(140) + 20 \cdot \text{LOG}(1575.42) = 69.0 \text{ dB}$ (**Worst case scenario**)

A **worst case scenario** is using the maximum antenna gain transmitted at the horizontal distance. In this case, at 100' beyond the nearest exterior wall, the power is as follows:

1. L1 Transmitted Power = **38.52 pW ERP= 63.2 pW EIRP** = -71.99 dBm/24 MHz (Based on maximum antenna gain)

At 100' = -71.99 - 69.0 = **-140.99 dBm/24 MHz (Worst case scenario, maximum antenna gain pointing horizontally out of the building)**
