

Explanation of Experiment and Need for STA

Raytheon Missile Systems (Raytheon) builds a variety of innovative technologies for the US government, including the Department of Defense and the various military services. Raytheon has been working on development of an advanced RF technology that uses one of its proprietary UAS platforms to search for, detect, and deliver reports that are needed by the customer. Initial testing and customer demonstrations have shown the promise of this technology. At this point, Raytheon needs to expand its field testing to incorporate some refinements into the system.

This application seeks authorization for testing in an area of Arizona that is primarily open desert. This testing will allow Raytheon to advance the development of the product much more rapidly.

Need for an STA

The testing to be conducted is expected to last for approximately 5 months, and therefore an STA is appropriate.

Technical Synopsis

- Spectrum Requested: 310-390 MHz, preferably 351 MHz and 362 MHz
- Area of Operation: 9.6 km radius around center location, primarily over open desert
- Test Time: approximately 2 hours per day
- Low power use: Transmitter operates at 1 W, the ERP for the mobile unit is only 2 W.

Description of Experiment

Raytheon is testing the operation of its UAS system incorporating data links that allow for the transmission of tracking information back to a command station.

The proposed testing is request two frequencies in the band from 310-390 MHz. The program is hoping to secure 351 MHz and 362 MHz. The goal is to test the performance of the UAS and radios using more than one channel to optimize data capture and transfer.

The radio selected is ideal for this use because it is a size and weight, less than an ounce, that can easily be accommodated by the UASs in use for this testing. The UASs are small, light, and quickly deployable, which makes them of great interest to the government customers. A larger, heavier radio would exceed the capabilities of the UAS to transport the radio.

The radios can carry data at a rate up to 1.2 Mbps. This provides incredible performance in a small package.

Spectrum Availability

Raytheon has worked with the DOD, in particular the Area Frequency Coordinator for Arizona (DOD AFC – AZ) and the Chairman of the Military Assignment Group (MAG), previously. Raytheon is aware that the frequencies sought in this application are virtually saturated in Arizona. Nevertheless, Raytheon is developing the technology for DOD customers, and it needs to build the system using radios that the DOD will be able to use successfully for this testing. Upon filing this application, Raytheon will seek guidance from both the DOD AFC – AZ and the MAG to ensure that the spectrum requested may be usable.

Power Levels and Antenna Gain

Raytheon has limited the power level of its proposed operations to only 2 Watts ERP for the mobile unit, and 12.162 Watts ERP for the directionalized command and control ground station. The command and control station has a higher gain antenna, with far less beamwidth, to ensure that it can capture the data transmissions from the UAS. The UAS has an omni-directional antenna, since that will be required in the field. It needs to have maneuverability, which means that the antenna has to transmit in all directions at any time. The command and control ground station can be oriented to follow the path of the UAS, and therefore can use the higher gain antenna, with less scatter of RF energy.

Limited Time of Use

The UASs will only be in use for two hours per day, which limits the amount of time that the spectrum will be in use. The radios will be in use full time during the flight testing.

The program is prepared to schedule its testing to accommodate the requirements of the DOD for use of these frequencies in Arizona.

Area of Operation

The proposed operations are expected to take place over the unoccupied areas within the radius of operations. This will give the program flexibility to operate within line of site of the ground control station.

Conclusion

Raytheon continues to work on the development of its UAS systems. This proposed testing will explore the use of a Microhard radio to deliver high speed data in real time. The testing is being

conducted in advance of a proposed RF technology demonstration that is scheduled to take place in the first quarter of 2017. Raytheon has designed its experimentation to minimize the spectrum and power needed for these operations.
