CALIBRATION CERTIFICATE

Object
CD835V3-SN: 1045

Calibration procedure(s)
QA CAL-20.v6
Calibration procedure for dipoles in air

Calibration date:
September 19, 2018

This calibration certificate documents the traceability to national standards, which realize the physical units of measurements (SI).
The measurements and the uncertainties with confidence probability are given on the following pages and are part of the certificate.

All calibrations have been conducted in the closed laboratory facility: environment temperature $(22 \pm 3)^{\circ} \mathrm{C}$ and humidity $<70 \%$.

American National Standard, Methods of Measurement of Compatibility between Wireless Communications Devices and Hearing Aids.

## Methods Applied and Interpretation of Parameters:

- Coordinate System: y-axis is in the direction of the dipole arms. z-axis is from the basis of the antenna (mounted on the table) towards its feed point between the two dipole arms. x-axis is normal to the other axes. In coincidence with the standards [1], the measurement planes (probe sensor center) are selected to be at a distance of 15 mm above the top metal edge of the dipole arms.
- Measurement Conditions: Further details are available from the hardcopies at the end of the certificate. All figures stated in the certificate are valid at the frequency indicated. The forward power to the dipole connector is set with a calibrated power meter connected and monitored with an auxiliary power meter connected to a directional coupler. While the dipole under test is connected, the forward power is adjusted to the same level.
- Antenna Positioning: The dipole is mounted on a HAC Test Arch phantom using the matching dipole positioner with the arms horizontal and the feeding cable coming from the floor. The measurements are performed in a shielded room with absorbers around the setup to reduce the reflections.
It is verified before the mounting of the dipole under the Test Arch phantom, that its arms are perfectly in a line. It is installed on the HAC dipote positioner with its arms parallel below the dielectric reference wire and able to move elastically in vertical direction without changing its relative position to the top center of the Test Arch phantom. The vertical distance to the probe is adjusted after dipole mounting with a DASY5 Surface Check job. Before the measurement, the distance between phantom surface and probe tip is verified. The proper measurement distance is selected by choosing the matching section of the HAC Test Arch phantom with the proper device reference point (upper surface of the dipole) and the matching grid reference point (tip of the probe) considering the probe sensor offset. The vertical distance to the probe is essential for the accuracy.
- Feed Point Impedance and Return Loss: These parameters are measured using a HP 8753E Vector Network Analyzer. The impedance is specified at the SMA connector of the dipole. The influence of reflections was eliminating by applying the averaging function while moving the dipole in the air, at least 70 cm away from any obstacles.
- E-field distribution: E field is measured in the $x$-y-plane with an isotropic ER3D-field probe with 100 mW forward power to the antenna feed point. In accordance with [1], the scan area is 20 mm wide, its length exceeds the dipole arm length ( 180 or 90 mm ). The sensor center is 15 mm (in z) above the metal top of the dipole arms. Two 3D maxima are available near the end of the dipole arms. Assuming the dipole arms are perfectly in one line, the average of these two maxima (in subgrid 2 and subgrid 8 ) is determined to compensate for any non-parallelity to the measurement plane as well as the sensor displacement. The E-field value stated as calibration value represents the maximum of the interpolated 3D-E-field, in the plane above the dipole surface.

The reported uncertainty of measurement is stated as the standard uncertainty of measurement multiplied by the coverage factor $\mathrm{k}=2$, which for a normal distribution corresponds to a coverage probability of approximately $95 \%$.

## Measurement Conditions

DASY system configuration, as far as not given on page 1.

| DASY Version | DASY5 | V52.10.1 |
| :--- | :---: | :---: |
| Phantom | HAC Test Arch |  |
| Distance Dipole Top - Probe Center | 15 mm |  |
| Scan resolution | $\mathrm{dx}, \mathrm{dy}=5 \mathrm{~mm}$ |  |
| Frequency | $835 \mathrm{MHz} \pm 1 \mathrm{MHz}$ |  |
| Input power drift | $<0.05 \mathrm{~dB}$ |  |

## Maximum Field values at 835 MHz

| E-field 15 mm above dipole surface | condition | Interpolated maximum |
| :--- | :---: | :---: |
| Maximum measured above high end | 100 mW input power | $109.3 \mathrm{~V} / \mathrm{m}=40.77 \mathrm{dBV} / \mathrm{m}$ |
| Maximum measured above low end | 100 mW input power | $108.2 \mathrm{~V} / \mathrm{m}=40.68 \mathrm{dBV} / \mathrm{m}$ |
| Averaged maximum above arm | 100 mW input power | $108.8 \mathrm{~V} / \mathrm{m} \pm \mathbf{1 2 . 8} \%(\mathbf{k}=\mathbf{2})$ |

## Appendix (Additional assessments outside the scope of SCS 0108)

## Antenna Parameters

| Frequency | Return Loss | Impedance |
| :--- | :---: | :---: |
| 800 MHz | 16.0 dB | $40.8 \Omega-11.3 \mathrm{j} \Omega$ |
| 835 MHz | 32.3 dB | $49.4 \Omega+2.3 \mathrm{j} \Omega$ |
| 880 MHz | 18.1 dB | $57.9 \Omega-11.0 \mathrm{j} \Omega$ |
| 900 MHz | 18.2 dB | $48.3 \Omega-12.1 \mathrm{j} \Omega$ |
| 945 MHz | 20.5 dB | $49.1 \Omega+9.3 \mathrm{j} \Omega$ |

### 3.2 Antenna Design and Handling

The calibration dipole has a symmetric geometry with a built-in two stub matching network, which leads to the enhanced bandwidth.
The dipole is built of standard semirigid coaxial cable. The internal matching line is open ended. The antenna is therefore open for DC signals.
Do not apply force to dipole arms, as they are liable to bend. The soldered connections near the feedpoint may be damaged. After excessive mechanical stress or overheating, check the impedance characteristics to ensure that the internal matching network is not affected.

After long term use with 40 W radiated power, only a slight warming of the dipole near the feedpoint can be measured.

## CD835V3, serial no. 1045 Extended Dipole Calibrations

Referring to KDB 450824, if dipoles are verified in return loss (<-20dB, within $20 \%$ of prior calibration), and in impedance (within 5 ohm of prior calibration), the annual calibration is not necessary and the calibration interval can be extended.
<Justification of the extended calibration>

| CD835V3 - serial no. 1045 |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 835MHZ |  |  |  |  |  |
| Date of Measurement | Return-Loss (dB) | Delta (\%) | Real Impedance (ohm) | Delta (ohm) | Imaginary Impedance (ohm) | Delta (ohm) |
| 09.19.2018 | -32.3 |  | 49.4 |  | 2.3 |  |
| 09.18.2019 | -29.104 | -9.89 | 48.042 | -1.358 | 1.772 | -0.528 |
| 09.17.2020 | -33.129 | 2.57 | 50.259 | -0.859 | 0.57221 | 1.72779 |

The return loss is <-20dB, within $20 \%$ of prior calibration; the impedance is within 5 ohm of prior calibration. Therefore the verification result should support extended calibration.

## CD1880V3, serial no. 1038 Extended Dipole Calibrations

Referring to KDB 450824, if dipoles are verified in return loss (<-20dB, within $20 \%$ of prior calibration), and in impedance (within 5 ohm of prior calibration), the annual calibration is not necessary and the calibration interval can be extended.
<Justification of the extended calibration>

| CD1880V3 - serial no. 1038 |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1730MHZ |  |  |  |  |  |
| Date of Measurement | Return-Loss (dB) | Delta (\%) | Real Impedance (ohm) | Delta (ohm) | Imaginary Impedance (ohm) | Delta (ohm) |
| 09.19.2018 | -22.9 |  | 55.7 |  | 5.1 |  |
| 09.18.2019 | -21.704 | -5.22 | 56.98 | 1.28 | 5.926 | 0.826 |
| 09.17.2020 | -20.861 | -8.9 | 56.653 | -0.953 | 5.4734 | -0.3734 |
|  | 1880MHZ |  |  |  |  |  |
| Date of Measurement | Return-Loss (dB) | Delta (\%) | Real Impedance (ohm) | Delta (ohm) | Imaginary Impedance (ohm) | Delta (ohm) |
| 09.19.2018 | -21.2 |  | 59.3 |  | 2 |  |
| 09.18.2019 | -21.662 | 2.18 | 58.318 | -0.982 | 2.923 | 0.923 |
| 09.17.2020 | -22.276 | 5.08 | 59.3 | -0.04 | 1.7621 | 0.2379 |

The return loss is <-20dB, within $20 \%$ of prior calibration; the impedance is within 5 ohm of prior calibration. Therefore the verification result should support extended calibration.

Object
Calibration procedure(s)

## CD2600V3-SN: 1010

## QA CAL-20.V7 Calibration Procedure for Validation Sources in air

Calibration date:

## March 14, 2019

This calibration certificate documents the traceability to national standards, which realize the physical units of measurements (SI).
The measurements and the uncertainties with confidence probability are given on the following pages and are part of the certificate.

All calibrations have been conducted in the closed laboratory facility: environment temperature $(22 \pm 3)^{\circ} \mathrm{C}$ and humidity $<70 \%$.

## Methods Applied and Interpretation of Parameters:

- Coordinate System: $y$-axis is in the direction of the dipole arms. $z$-axis is from the basis of the antenna (mounted on the tabie) towards its feed point between the two dipole arms. $x$-axis is normal to the other axes. In coincidence with the standards [1], the measurement planes (probe sensor center) are selected to be at a distance of 15 mm above the top metal edge of the dipole arms.
- Measurement Conditions: Further details are available from the hardcopies at the end of the certificate. All figures stated in the certificate are valid at the frequency indicated. The forward power to the dipole connector is set with a calibrated power meter connected and monitored with an auxiliary power meter connected to a directional coupler. While the dipole under test is connected, the forward power is adjusted to the same level.
- Antenna Positioning: The dipole is mounted on a HAC Test Arch phantom using the matching dipole positioner with the arms horizontal and the feeding cable coming from the floor. The measurements are performed in a shielded room with absorbers around the setup to reduce the reflections.
It is verified before the mounting of the dipole under the Test Arch phantom, that its arms are perfectly in a line. It is installed on the HAC dipole positioner with its arms parallel below the dielectric reference wire and able to move elastically in vertical direction without changing its relative position to the top center of the Test Arch phantom. The vertical distance to the probe is adjusted after dipole mounting with a DASY5 Surface Check job. Before the measurement, the distance between phantom surface and probe tip is verified. The proper measurement distance is selected by choosing the matching section of the HAC Test Arch phantom with the proper device reference point (upper surface of the dipole) and the matching grid reference point (tip of the probe) considering the probe sensor offset. The vertical distance to the probe is essential for the accuracy.
- Feed Point Impedance and Return Loss: These parameters are measured using a HP 8753E Vector Network Analyzer. The impedance is specified at the SMA connector of the dipole. The influence of reflections was eliminating by applying the averaging function while moving the dipole in the air, at least 70 cm away from any obstacles.
- E-field distribution: E field is measured in the $x$-y-plane with an isotropic ER3D-field probe with 100 mW forward power to the antenna feed point. In accordance with [1], the scan area is 20 mm wide, its length exceeds the dipole arm length ( 180 or 90 mm ). The sensor center is 15 mm (in z ) above the metal top of the dipole arms. Two 3D maxima are available near the end of the dipole arms. Assuming the dipole arms are perfectly in one line, the average of these two maxima (in subgrid 2 and subgrid 8 ) is determined to compensate for any non-parallelity to the measurement plane as well as the sensor displacement. The E-field value stated as calibration value represents the maximum of the interpolated 3D-E-field, in the plane above the dipole surface.

The reported uncertainty of measurement is stated as the standard uncertainty of measurement multiplied by the coverage factor $k=2$, which for a normal distribution corresponds to a coverage probability of approximately $95 \%$.

## Measurement Conditions

| Averaged maximum above arm | 100 mW input power | $\mathbf{8 4 . 5 \mathrm { V } / \mathrm { m } \pm \mathbf { 1 2 . 8 } \% ( \mathbf { k } = \mathbf { 2 } )}$ |

## Appendix (Additional assessments outside the scope of SCS 0108)

## Antenna Parameters

| Frequency | Return Loss | Impedance |
| :--- | :---: | :---: |
| 2450 MHz | 24.0 dB | $45.3 \Omega-3.7 \mathrm{j} \Omega$ |
| 2550 MHz | 30.7 dB | $52.4 \Omega+1.8 \mathrm{j} \Omega$ |
| 2600 MHz | 26.5 dB | $54.8 \Omega-1.1 \mathrm{j} \Omega$ |
| 2650 MHz | 25.2 dB | $52.5 \Omega-5.0 \mathrm{j} \Omega$ |
| 2750 MHz | 19.9 dB | $46.3 \Omega-9.0 \mathrm{j} \Omega$ |

### 3.2 Antenna Design and Handling

The calibration dipole has a symmetric geometry with a built-in two stub matching network, which leads to the enhanced bandwidth.
The dipole is built of standard semirigid coaxial cable. The internal matching line is open ended. The antenna is therefore open for DC signals.
Do not apply force to dipole arms, as they are liable to bend. The soldered connections near the feedpoint may be damaged. After excessive mechanical stress or overheating, check the impedance characteristics to ensure that the internal matching network is not affected.

After long term use with 40 W radiated power, only a slight warming of the dipole near the feedpoint can be measured.

## CD3500V3, serial no. 1009 Extended Dipole Calibrations

Referring to KDB 450824, if dipoles are verified in return loss (<-20dB, within $20 \%$ of prior calibration), and in impedance (within 5 ohm of prior calibration), the annual calibration is not necessary and the calibration interval can be extended.
<Justification of the extended calibration>

| CD3500V3 - serial no. 1009 |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 3500MHZ |  |  |  |  |  |
| Date of Measurement | Return-Loss (dB) | Delta (\%) | Real Impedance (ohm) | Delta (ohm) | Imaginary Impedance (ohm) | Delta (ohm) |
| 02.18.2019 <br> (Cal. Report) | -24.698 |  | 52.048 |  | -5.5853 |  |
| $\begin{aligned} & 02.17 .2020 \\ & \text { (extended) } \end{aligned}$ | -23.48 | -4.932 | 55.132 | -3.084 | -4.9272 | -0.6581 |

The return loss is $<-20 \mathrm{~dB}$, within $20 \%$ of prior calibration; the impedance is within 5 ohm of prior calibration. Therefore the verification result should support extended calibration.

## Methods Applied and Interpretation of Parameters：

－Coordinate System：$y$－axis is in the direction of the dipole arms．z－axis is from the basis of the antenna （mounted on the table）towards its feed point between the two dipole arms．$x$－axis is normal to the other axes． In coincidence with the standards［1］，the measurement planes（probe sensor center）are selected to be at a distance of 15 mm above the top metal edge of the dipole arms．
－Measurement Conditions：Further details are available from the hardcopies at the end of the certificate．All figures stated in the certificate are valid at the frequency indicated．The forward power to the dipole connector is set with a calibrated power meter connected and monitored with an auxiliary power meter connected to a directional coupler．While the dipole under test is connected，the forward power is adjusted to the same level．
－Antenna Positioning：The dipole is mounted on a HAC Test Arch phantom using the matching dipole positioner with the arms horizontal and the feeding cable coming from the floor．The measurements are performed in a shielded room with absorbers around the setup to reduce the reflections．
It is verified before the mounting of the dipole under the Test Arch phantom，that its arms are perfectly in a line．It is installed on the HAC dipole positioner with its arms parallel below the dielectric reference wire and able to move elastically in vertical direction without changing its relative position to the top center of the Test Arch phantom．The vertical distance to the probe is adjusted after dipole mounting with a DASY5 Surface Check job．Before the measurement，the distance between phantom surface and probe tip is verified．The proper measurement distance is selected by choosing the matching section of the HAC Test Arch phantom with the proper device reference point（upper surface of the dipole）and the matching grid reference point（tip of the probe）considering the probe sensor offset．The vertical distance to the probe is essential for the accuracy．
－Feed Point Impedance and Return Loss：These parameters are measured using a HP 8753E Vector Network Analyzer．The impedance is specified at the SMA connector of the dipole．The influence of reflections was eliminating by applying the averaging function while moving the dipole in the air，at least 70 cm away from any obstacles．
－E－field distribution：E field is measured in the $x$－$y$－plane with an isotropic ER3D－field probe with 100 mW forward power to the antenna feed point．In accordance with［1］，the scan area is 20 mm wide，its length exceeds the dipole arm length（ 180 or 90 mm ）．The sensor center is 15 mm （in z）above the metal top of the dipole arms．Two 3D maxima are available near the end of the dipole arms．Assuming the dipole arms are perfectly in one line，the average of these two maxima（in subgrid 2 and subgrid 8 ）is determined to compensate for any non－parallelity to the measurement plane as well as the sensor displacement．The E－field value stated as calibration value represents the maximum of the interpolated 3D－E－field，in the plane above the dipole surface．

The reported uncertainty of measurement is stated as the standard uncertainty of measurement multiplied by the coverage factor $\mathrm{k}=2$ ，which for a normal distribution corresponds to a coverage probability of approximately $95 \%$ ．

## Measurement Conditions

DASY system configuration, as far as not given on page 1.

| 5800 MHz | 21.4 dB | $42.8 \Omega+3.1 \mathrm{j} \Omega$ |
| 5900 MHz | 21.3 dB | $47.5 \Omega+8.1 \mathrm{j} \Omega$ |

### 3.2 Antenna Design and Handling

The calibration dipole has a symmetric geometry with a built-in two stub matching network, which leads to the enhanced bandwidth.
The dipole is built of standard semirigid coaxial cable. The internal matching line is open ended. The antenna is therefore open for DC signals.
Do not apply force to dipole arms, as they are liable to bend. The soldered connections near the feedpoint may be damaged. After excessive mechanical stress or overheating, check the impedance characteristics to ensure that the internal matching network is not affected.

After long term use with 40 W radiated power, only a slight warming of the dipole near the feedpoint can be measured.

## DASY5 E-field Result
