A wideband power sensor was connected on the RF output port of the EUT.

The response of the power sensor is then read by software on a computer and the gate function is used in order to determine the output power during ON time only.

This measure is repeated for each port of the EUT .

Then the results were summed in linear power unit for mode g and n.

**Equipment under test operating condition:**

The equipment under test is blocked in continuous modulated transmission mode, at the highest output power level at which the transmitter is intended to operate (see §2).

We used for power source the internal fully charged battery

Conducted measure are realized with the method 12.2.2

Average measure are realized with the method 12.2.5

**Test set up:**

The measure is realized first in conducted on each port of the product then repeated in radiated for measure of cabinet spurious

For cabinet spurious measurement the antennas ports are fitted with 50 ohm non-reactive load.

Except for band 2.15 GHz to 2.75 GHz, the measure is directly realized in radiated with the antennas of the product.

**Frequency range:** From 9 kHz to 10<sup>th</sup> harmonic of the highest fundamental frequency (25 GHz)**Detection mode:** Quasi-peak (F < 1 GHz)

Peak / Average (F &gt; 1 GHz)

**Bandwidth:** 200Hz (9 kHz < F < 150kHz)

9 kHz (150 kHz &lt; F &lt; 30MHz)

120 kHz (30 MHz &lt; F &lt; 1 GHz)

100 kHz / 1 MHz (F &gt; 1 GHz)

**Distance of antenna:** 10 m below 1 GHz

3 m between 1 GHz and 18 GHz

1 m between 18 GHz and 25 GHz

### Conducted method

The equipment under test is connected to the measuring equipment via a 50  $\Omega$  attenuator.

Bandwidth: 200Hz (9 kHz < F < 150kHz)  
9 kHz (150 kHz < F < 30MHz)  
120 kHz (30 MHz < F < 1 GHz)  
100 kHz / 1 MHz (F > 1 GHz)

The spurious are measured (in dBm) and the antenna gain is added (2.5 dBi) in order to determine the EIRP

The appropriate maximum ground reflection factor is added to the EIRP level (6 dB for frequencies  $\leq$  30 MHz, 4.7 dB for frequencies between 30 MHz and 1000 MHz, inclusive and 0 dB for frequencies > 1000 MHz).

The measure is realized on each individual chain  
The EIRP of all chains is summed in linear terms for mode g and n.

And the resultant EIRP level is converted to an equivalent electric field strength using the following relationship:

$$E = \text{EIRP} - 20\log D + 104.8$$

Where: E = electric field strength in dB $\mu$ V/m,  
EIRP = equivalent isotropic radiated power in dBm  
D = specified measurement distance in meters.

### Radiated method

First an exploratory radiated measurement was performed. During this phase the product is oriented in three orthogonal planes.

Then the final measurement is realized with the product on the most critical orientation.

The measure is realized on open area test site under 1 GHz and in anechoic chamber above 1 GHz.

When the system is tested in an open area test site (OATS), the EUT is placed on a rotating table, 0.8m from a ground plane.

When the system is tested in anechoic chamber, the EUT is placed on a rotating table, 1.65 m or 1.5 m from a ground plane.

Zero degree azimuths correspond to the front of the device under test.

For mode b the measure is realized on the two different chains separately.

**Antenna height:** 1 to 4 meters (in open area test site) / 1.65 or 1.5 meter (in anechoic room)

**Antenna polarization:** vertical and horizontal (only the highest level is recorded)

**Equipment under test operating condition:**

The equipment under test is blocked in continuous modulated transmission mode, at the highest output power level at which the transmitter is intended to operate.

We used for power source the internal fully charged battery

Duty cycle factor for average measurement is then added. (Correction=  $10 \log (1/X)$ )

This factor is already included on the results (tables and graphs)

For detailed results at  $\pm 2$  MHz of the edge of the band see §8.

**Applicable limits:** In any 100 kHz bandwidth outside the frequency band in which the spread spectrum or digitally modulated intentional radiator is operating, the radio frequency power that is produced by the intentional radiator shall be at least 30 dB below that in the 100 kHz bandwidth within the band that contains the highest level of the desired power.

In addition, radiated emissions which fall in the restricted band, as defined in section 15.205 (a), must also comply with the radiated emission limits specified in section 15.209 (a) (see section 15.205 (c)).

**Test conclusion:**

RESPECTED STANDARD

<b>11. MAXIMUM CONDUCTED POWER DENSITY</b>
--

Temperature (°C) : 23

Humidity (%HR): 41

Date : April 16, 2018 to  
April 18, 2018

Technician : T. LEDRESSEUR

Standard: FCC Part 15

Test procedure: paragraph 15.247 (e)

Method: AVGPSD-2 of paragraph 10.5 of KDB 558074

Test set up:

Bandwidth selected	10 MHz	20 MHz
Span	20 MHz	40 MHz
RBW	10 kHz	10 kHz
VBW	30 kHz	30 kHz
detector	RMS	RMS
Points	5001	10001
Trace mode	Avg power	Avg power
Number of traces	100	100

The measure is repeated on each output port of the EUT. Then the results were summed in linear power unit for mode g and n.

**Equipment under test operating condition:**

The equipment under test is blocked in continuous modulated transmission mode, at the highest output power level at which the transmitter is intended to operate.

We used for power source the internal fully charged battery

- According with KDB 662911 the antenna gain is calculated as follow:

Total gain = antenna gain (dBi) + array gain

With Array Gain =  $10 \log(\text{NANT}/\text{NSS})$  dB = 3 and with NANT=2 and NSS=1

Total gain = 2.5 +3 = 5.5 dBi

- See appendix for plot

- In addition during the measure the duty cycle for all mode is adjusted as follow:

Dutyc cycle factor =  $10 \log(1/x)$
