15.247(a)(1) that the rx input bandwidths shift frequencies in synchronization with the transmitted signals.

15.247(g): In accordance with the Bluetooth Industry Standard, the system is designed to comply with all of the regulations in Section 15.247 when the transmitter is presented with a continuous data (or information) system.

15.247(h): In accordance with the Bluetooth Industry Standard, the system does not coordinate it channels selection/ hopping sequence with other frequency hopping systems for the express purpose of avoiding the simultaneous occupancy of individual hopping frequencies by multiple transmitters.

Pseudorandom frequency hopping sequence

The channel is represented by a pseudo-random hopping sequence hopping through the 79 RF channels. The hopping sequence is unique for the piconet and is determined by the Bluetooth device address of the master; the phase in the hopping sequence is determined by the Bluetooth clock of the master. The channel is divided into time slots where each slot corresponds to an RF hop frequency. Consecutive hops correspond to different RF hop frequencies. The nominal hop rate is 1 600 hops/s.

Equal hopping frequency use

The channels of this system will be used equally over the long-term distribution of the hopsets.

System receiver input bandwidth

Each channel bandwidth is 1 Mz.

The system receivers have input bandwidths that match the hopping channel bandwidths of their corresponding transmitters and shift frequencies in synchronization with the transmitted signals.

1.2. Test configuration

1.8. Measurement results explanation example

For all conducted test items

The offset level is set in the spectrum analyzer to compensate the RF cable loss and attenuator factor between EUT conducted output port and spectrum analyzer. With the offset compensation, the spectrum analyzer reading level is exactly the EUT RF output level.

Offset(dB) = RF cable loss(dB) + attenuator factor(dB). = 1.12 + 10 = 11.12

1.9. Measurement Uncertainty

Uncertainty for Conduction emission test		2.62 dB
Uncertainty for Radiation emission test (include Fundamental emission)	9kHz - 30MHz	4.54 dB

Test procedure

- 1. The EUT is placed on a turntable, which is 0.8 m (below 1 Hz) and 1.5 m (above 1 Hz) ground plane.
- 2. The turntable shall be rotated for 360 degrees to determine the position of maximum emission level.
- 3. EUT is set 3 m away from the receiving antenna, which is varied from 1m to 4m to find out the highest emissions.
- 4. Maximum procedure was performed on the six highest emissions to ensure EUT compliance.
- 5. And also, each emission was to be maximized by changing the polarization of receiving antenna both horizontal and vertical.
- 6. Repeat above procedures until the measurements for all frequencies are complete.
- 7. Spectrum analyzer settings for f < 1 GHz:

Span = wide enough to fully capture the emission being measured

RBW = 100 kHz

 $VBW \ge RBW$

Sweep = auto

Detector function = quasi peak

Trace = max hold

8. Spectrum analyzer settings for $f \ge 1$ GHz: Peak

Span = wide enough to fully capture the emission being measured

RBW = 1 Mz

 $VBW \ge RBW$

Sweep = auto

Detector function = peak

Trace = max hold

9. Spectrum analyzer settings for $f \ge 1$ GHz: Average

Average value of pulsed emissions.

Unless otherwise specified, when the radiated emission limits are expressed in terms of the average value of the emission and pulsed operation is employed, the average measurement shall determined from the peak field strength after correcting for the worst-case duty cycle as described in 7.5 in ANSI 63.10-2013 & Procedure 9(b) in the KDB 558074 v05r02.

- 10. Duty Cycle Correction Factor (AFH with 20 channel hopping is the worst case.)
 - a. Time to cycle through all channels = $\Delta t = \tau [ms] \times 20$ channels = 58.28 ms, where $\tau = pulse$ width
 - b. 100 ms/ Δt [ms] = H \rightarrow Round up to next highest integer, H '=2
 - c. Worst Case Dwell Time = τ [ms] × H' = 5.828 ms
 - d. Duty Cycle Correction = 20log (Worst Case Dwell Time/ 100ms) dB = -24.69 dB
- 11. Both 2Mbps & 3Mbps data rate were investigated. Only the radiated emissions of the configuration that produced the worst case emissions are reported in this section.

Note:

- 1. The spectrum is measured from 9 kHz to the 10th harmonic of the fundamental frequency of the transmitter using CISPR quasi peak detector below 1 GHz. Above 1 GHz, average and peak measurements were taken using linearly polarized horn antennas. The worst-case emissions are reported however emissions whose levels were not within 20 dB of the respective limits were not reported.
- 2. The loop antenna was investigated with three polarizations, and horizontal polarizations were reported as the worst case.
- 3. When Average result is different from peak result over 20 dB (over-averaging), according to 15.35 (c), as a "duty cycle correction factor", pulse averaging with 20 log(duty cycle) has to be used.

 Duty cycle correction factor = 20log(dwell time/100 ms)
- 5. Average test would be performed if the peak result were greater than the average limit.
- 6. Field strength($dB\mu V/m$) = Level($dB\mu V$) + Correction factors(dB/m) + Cable loss(dB) + or $F_d(dB)$
- 7. Correction factors(dB/m) = Antenna factor(dB/m) + Cable loss(dB) + or Amp. gain(dB)
- 8. Margin(dB) = Limit(dB μ V/m) Field strength(dB μ V/m)
- 9. The fundamental of the EUT was investigated in three orthogonal orientations X, Y and Z, it was determined that $\underline{\mathbf{X}}$ orientation was worst-case orientation; therefore, all final radiated testing was performed with the EUT in $\underline{\mathbf{X}}$ orientation.
- 10. The worst-case emissions are reported however emissions whose levels were not within 20 dB of respective limits were not reported.
- 11. According to exploratory test no any obvious emission were detected from 9 kHz to 30 MHz. Although these tests were performed other than open field test site, adequate comparison measurements were confirmed against 30 m open field test site. Therefore sufficient tests were made to demonstrate that the alternative site produces results that correlate with the ones of tests made in an open field based on KDB 414788.
- 12. $f < 30\,$ MHz, extrapolation factor of 40 dB/decade of distance. $F_d = 40log(D_m / Ds)$ $f \ge 30\,$ MHz, extrapolation factor of 20 dB/decade of distance. $F_d = 20log(D_m / Ds)$ Where:

 F_d = Distance factor in dB

 D_m = Measurement distance in meters

D_s = Specification distance in meters

3.7. Conducted band edge and out of band emissions

Test procedure

ANSI C63.10-2013 - Section 7.8.4 and 7.8.8

EUT Attenuator Spectrum analyzer

Test setting

- 1. Span = wide enough to capture the peak level of the in-band emission and all spurious emissions(e.g., harmonics) from the lowest frequency generated in the EUT up through the 10th harmonic.
- 2. RBW = 100 kHz
- 3. VBW ≥ 300 kHz
- 4. Detector = Peak
- 5. Number of sweep points $\geq 2 \times \text{Span/RBW}$
- 7. Trace mode = max hold
- 8. Sweep time = auto couple
- 9. The trace was allowed to stabilize

Limit

According to 15.247(d), in any 100 kHz bandwidth outside the frequency band in which the spread spectrum or digitally modulated intentional radiator is operating, the radio frequency power that is produced by the intentional radiator shall be at least 20 dB below that in the 100 kHz bandwidth within the band that contains the highest level of the desired power, based on either an RF conducted or a radiated measurement, provided the transmitter demonstrates compliance with the peak conducted power limits. If the transmitter complies with the conducted power limits based on the use of RMS averaging over a time interval, as permitted under paragraph(b)(3) of this section, the attenuation required under this paragraph shall be 30 dB instead of 20 dB. Attenuation below the general limits specified in section 15.209(a) is not required. In addition, radiated emission which in the restricted band, as define in section 15.205(a), must also comply the radiated emission limits specified in section 15.209(a) (see section 15.205(c))
