## 3.3 Occupied Bandwidth (FCC Rule § 2.1049)

### 3.3.1 Measuring Method

FCC rule 47 CFR 2.1049 requires measurements of the occupied bandwidth which is defined in the same section as "the frequency bandwidth such that, below its lower and above its upper frequency limits, the mean powers radiated are each equal to 0.5 percent of the total mean power radiated by a given emission." To obtain the occupied bandwidth of the radar transmitter, a special program (program list shown below) was loaded to the Hewlett-Packard spectrum analyzer and run by entering the HP-provided POWER BANDWIDTH calculation command [PWRBW].

The result was automatically displayed on the screen on the spectrum analyzer as:

POWER\_BW=---- MHz

"Lower limit frequency of the authorized band",  $f(\text{LAUBW}) = f_0 - f(\text{AUBW})/2 = 9360$  MHz

3) Assignable frequency bandwidth : 200 MHz (between 9300 MHz and 9500 MHz)

(FCC Rule § 80.375 (d)-(1))

"Upper limit frequency of the assignable band",  $f(\text{UASB}) = 9500$  MHz

"Lower limit frequency of the assignable band",  $f(\text{LASB}) = 9300$  MHz

4) Guard Band ( $f(1.5/T)$ ) :

Pulselength	Short	Middle	Long
Range Scale (nm)	0.25	2	36
Pulselength ( $\mu$ sec)	0.08	0.30	0.80
Guard Band $f(1.5/T)$ (MHz)	18.75	5.00	1.88

### 3.6.5 Test Results:

(2) "Lower Tolerance Frequency measured (at  $+50^\circ\text{C}$ )",  $f(\text{L}) = 9404.1$  MHz

(3)-(a)

$f(\text{U}) + \text{max. } f(1.5/T) = 9437.04$  MHz  $< f(\text{UAUBW}) = 9460$  MHz  $\leq f(\text{UASB}) = 9500$  MHz

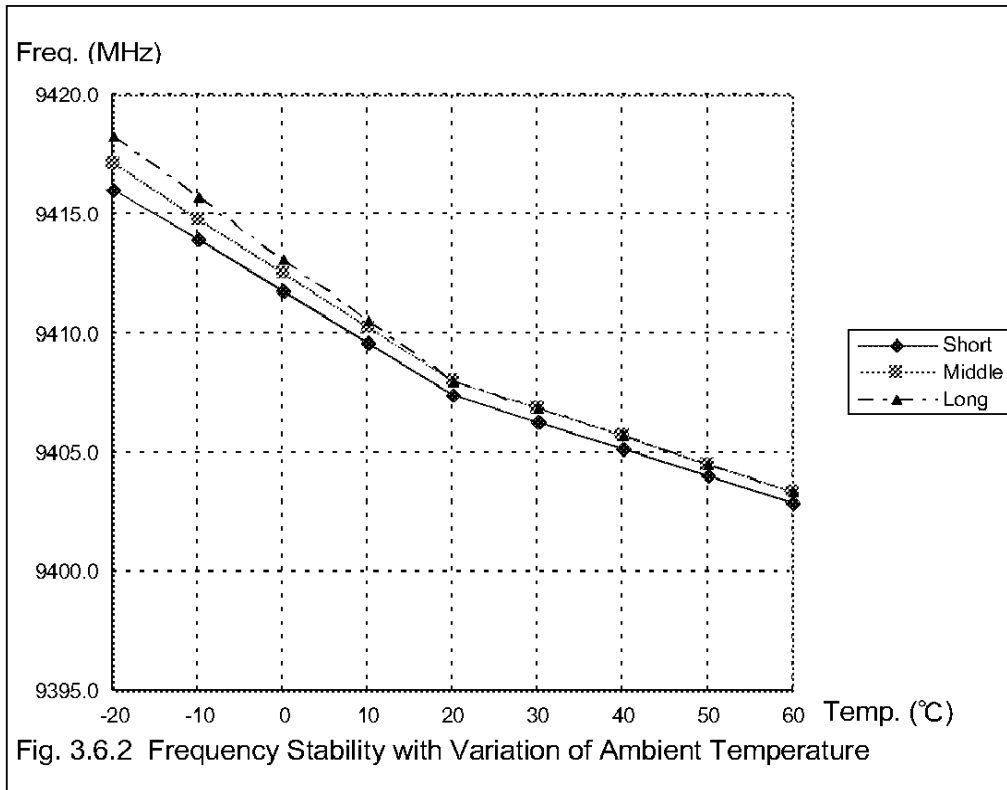

(3) - (b)

$f(\text{L}) - \text{max. } f(1.5/T) = 9385.32$  MHz  $> f(\text{LAUBW}) = 9360$  MHz  $\geq f(\text{LASB}) = 9300$  MHz

So, both are found within the specified limits.

## 5.2 Description of the circuits employed for suppression of spurious radiation, for limiting or shaping the control pulse, and for limiting or controlling power

### ANTENNA UNIT

TRANSCEIVER MODULE (RTR-051)

#### Modulator PCB MD9052

The primary function of the modulator is to produce narrow high-tension pulses to drive the magnetron. To produce such pulses, the modulator board incorporates a modulator trigger circuit, a modulating pulse generator and a booster pulse transformer.

The modulator trigger circuit is composed of U811 and associated components. It generates pulses that fire modulator FET Q801. Normally, the circuit is stable with U811 off. The pulse to fire the modulator FET is produced when U811 turns on upon receiving the TX trigger pulse from the display unit. When U811 turns on at the positive-going edge of the TX trigger pulse, it produces a narrow pulse. This narrow pulse is boosted by pulse transformer T802 by the ratio 1 :16. The resultant pulse, its level being 2.2 kV, is provided to limit the magnetron current.

CR803 and CR804 absorb the ringing in the secondary side of T801 while C807 decouples the pulse energy that is liable to occur across the magnetron heater when T801's secondary windings are unbalanced or the load is asymmetric.

Also incorporated in the modulator board are the TX HV circuit and magnetron heater power supply circuit. The TX HV circuit provides a high-tension of about 300 V to the pulse forming network through CR802 and CR807. A DC voltage of 8.0 V is supplied to the magnetron heater through CR801.

#### Duplexer and Frequency Converter (in Scanner unit)

The microwave energy produced by the magnetron enters the circulator from port 2. It is fed to port 3 with a negligible loss of energy; port 1 at this time is isolated. In the same manner, the received signal entering into port 3 is transferred to port 1, isolating port 2.

This operation of the circulator protects the receiver during transmission and minimizes the loss of the received signal. Thus, the circulator allows a single antenna radiator to be used for transmission and reception of radar signals.

A diode limiter, made up of a pair of PIN diodes, is incorporated in the first stage of the MIC (microwave IC, U801). It is a passive switching device which allows the low-level RF signal to pass through and prohibits relatively strong microwave energy, such as the leak from the magnetron. It also protects the sensitive amplifier from pulses received directly from other radars operating in the proximity.

When a low-level signal is received, the PIN diodes remain in the cutoff state, and the limiter's input impedance matches the characteristic impedance of the receiver allowing the signal to be delivered to the frequency converter of U801. When strong microwave energy is received, the PIN diodes are put in the conductive state (or short-circuited) causing the input energy to be attenuated. The strong input is further reduced to about 150 mW by the varacter diode.

The MIC converts 9 GHz RF signal into an intermediate frequency of 60 MHz. It is achieved by

mixing the received signal with the local oscillator signal in the frequency converter of the MIC. The built-in local oscillator oscillates at a frequency 60 MHz higher than the magnetron frequency of 9410 MHz.

## IF Amplifier Board IF7758

The detected 60 MHz IF signal is amplified by the RF amplifier, the output of which is delivered to the display unit video amplifier. The 60MHz IF signal from the MIC is fed to the base of Q601 through C601.

The signal from Q602 is fed to the broad band amplifier U601. The output of U601 is inductively coupled to the second-stage broad band amplifier U602.

GAIN/STC signals are applied respectively to U601 pin 16 and pin 13 via the STC circuit. The output of U602 is then coupled to video detector Q604. The video signal is taken from the emitter of Q605 through C632, and sent to the display via the video cable.

The IF amplifier PCB also incorporates an STC circuit. The STC circuit made up of Q610, Q611 and Q612 changes the gain of the IF amplifier in the function of time so that the gain is minimum at the time of transmission and increases gradually to maximum gain with time (range).

The amount of current flowing into Q612 is determined by the time constant of the parallel-series capacitor/ resistor network consisting of C641 - C643, R637 - R640. It gradually decreases as the capacitors are discharged. The rate of discharge is inversely proportional to "t", the elapsed time after transmission. The current flowing into Q612 is also controlled by the base potential in addition to the time constant of the capacitor/ resistor network.

The time-varying waveform produced at the emitter of Q612 is de-restored by the STC control potentiometer (located in the display) and applied to U601 pin 13.
