## CERTIFICATE OF COMPLIANCE (SAR EVALUATION)

OKI Telecom Inc.  
437 Old Peachtree Blvd.  
Suwanee, GA 30174  
Attn: H. Akiyama – Director, Product Engineering

Dates of Tests: March 30 – April 01, 1998  
Test Report S/N: SAR.980326234.B2J  
Test Site: PCTEST Lab, Columbia, MD

FCC ID

**B2JUM9106**

APPLICANT

**OKI TELECOM INC.**

EUT Type:	Dual Mode Cellular Phone (AMPS/CDMA)
Tx Frequency:	824 - 849 MHz
Max. Output Power:	0.6W (AMPS) / 0.32W (CDMA)
Trade Name / Model:	OKI UM9106
FCC Classification:	Non-Broadcast Transmitter Held to Ear (TNE)
Application Type:	Type Acceptance
Serial Number:	n/a (pre-production)
FCC Rule Part(s):	2.1093; ET Docket 96.326; 22(H)

This wireless portable device has been shown to be capable of compliance for localized specific absorption rate (SAR) for uncontrolled environment/ general population exposure limits specified in ANSI/IEEE Std. C95.1-1992 and has been tested in accordance with the measurement procedures specified in ANSI/IEEE Std C95.3-1992 (see Test Report).

I attest to the accuracy of data. All measurements reported herein were performed by me or were made under my supervision and are correct to the best of my knowledge and belief. I assume full responsibility for the completeness of these measurements and vouch for the qualifications of all persons taking them.

NVLAP accreditation does not constitute any product endorsement by NVLAP or any agency of the United States Government.

PCTEST certifies that no party to this application has been denied the FCC benefits pursuant to Section 5301 of the Anti-Drug Abuse Act of 1988, 21 U.S.C. 853(a).

Lab Code 100431-0

<sup>1</sup> Specific Absorption Rate (SAR) is a measure of the rate of energy absorption due to exposure to an RF transmitting source (wireless portable device).

<sup>2</sup> IEEE/ANSI Std. C95.1-1992 limits are used to determine compliance with FCC ET-Docket 93-62.

## 1.1 INTRODUCTION

The FCC has adopted the guidelines for evaluating the environmental effects of radiofrequency radiation in ET Docket 93-62 on Aug. 6, 1996 to protect the public and workers from the potential hazards of RF emissions due to FCC-regulated portable devices.[1]

The safety limits used for the environmental evaluation measurements are based on the criteria published by the American National Standards Institute (ANSI) for localized specific absorption rate (SAR) in *IEEE/ANSI C95.1-1992 Standard for Safety Levels with Respect to Human Exposure to Radio Frequency Electromagnetic Fields, 3 kHz to 300 GHz*. (c) 1992 by the Institute of Electrical and Electronics Engineers, Inc., New York, New York 10017.[2] The measurement procedure described in *IEEE/ANSI C95.3-1992 Recommended Practice for the Measurement of Potentially Hazardous Electromagnetic Fields - RF and Microwave*[3] is used for guidance in measuring SAR due to the RF radiation exposure from the Equipment Under Test (EUT). These criteria for SAR evaluation are similar to those recommended by the National Council on Radiation Protection and Measurements (NCRP) in *Biological Effects and Exposure Criteria for Radiofrequency Electromagnetic Fields*, NCRP Report No. 86 (c) NCRP, 1986, Bethesda, MD 20814.[4] SAR is a measure of the rate of energy absorption due to exposure to an RF transmitting source. SAR values have been related to threshold levels for potential biological hazards.

Specific Absorption Rate (SAR) is defined as the time derivative (rate) of the incremental energy ( $dU$ ) absorbed by (dissipated in) an incremental mass ( $dm$ ) contained in a volume element ( $dV$ ) of a given density ( $\rho$ ). It is also defined as the rate of RF energy absorption per unit mass at a point in an absorbing body (see Fig. 2).

$$SAR = \frac{d}{dt} \left( \frac{dU}{dm} \right) = \frac{d}{dt} \left( \frac{dU}{\rho dV} \right)$$

Figure 2. SAR Mathematical Equation

**SAR is expressed in units of Watts per Kilogram (W/kg).**

$$SAR = \sigma E^2 / \rho$$

where:

$\sigma$	=	conductivity of the tissue-simulant material (S/m)
$\rho$	=	mass density of the tissue-simulant material (kg/m <sup>3</sup> )
$E$	=	Total RMS electric field strength (V/m)

NOTE: The primary factors that control rate of energy absorption were found to be the wavelength of the incident field in relations to the dimensions and geometry of the irradiated organism, the orientation of the organism in relation to the polarity of field vectors, the presence of reflecting surfaces, and whether conductive contact is made by the organism with a ground plane.[4]

## 2.1 SAR MEASUREMENT SET-UP

PCTEST Lab SAR measurement system consists of completely automated robotics system, cell controller (Pentium Pro 200 computer), E-field probe, and phantom containing the brain equivalent material. The robot is a six-axis industrial robot performing precise movements to position the probe to the location (points) of maximum electromagnetic field (EMF) (see Fig. 3).

The Robot table consists of the power supply, robot controller, safety computer, teach pendant (Joystick), six-axis robot arm, and the probe. The cell controller consists of PCTEST Pentium-Pro 200 MHz computer with Windows NT system and SAR Measurement software, National Instruments analog card, NEC monitor, keyboard, and mouse. The robot controller is connected to the cell controller to communicate between the two computers. The probe data is connected to the cell controller via high-impedance carbon-fiber cable to avoid field distortions and minimize external noise from interfering with the data.

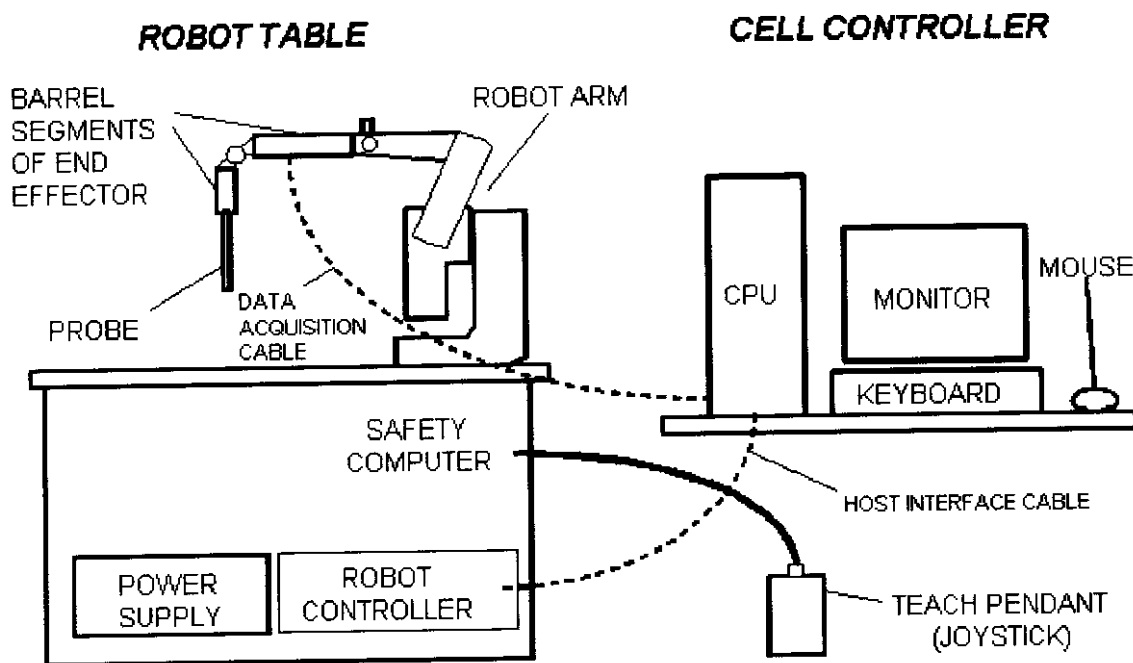

Figure 3. PCTEST Robotics SAR Test Measurement Set-up

When the Robot is in the home position, the Y-axis of the coordinate system parallels the line of intersection between the tabletop and the long axis of the Robot's Large Shoulder. The Teach Pendant may be used to establish the X,Y coordinate directions by depressing the 0-X and 0-Y MOTOR/AXIS switches while in axis mode.

The robot is first taught to position the probe sensor following a specific pattern of points. In the first sweep the sensor enclosure touches the inside of the phantom head. The SAR is measured on a defined grid of points which are concentrated on the surface of the head closest to the antenna of the transmitting device (EUT).

### 3.1 ISOTROPIC E-FIELD PROBE SYSTEM

---

The near-field probe is an implantable isotropic E-field probe that measures the voltages proportional to the  $|E|^2$  (electric) or  $|H|^2$  (magnetic) fields. The probe is enclosed in a hollow plastic protective cylinder 9 mm. outer diameter, 0.5 mm. thickness and 30 cm. in length. This SAR measurement system and the probe are similar to the one developed by Motorola.[8] The E-probe contains three electrically small array of orthogonal dipoles strategically placed to provide greater accuracy and to compensate for near-field spatial gradients. The probe contains diodes which are placed over the gap of the dipoles to improve RF detection. The electrical signal detected by each diode is amplified by three dc amplifiers and are contained in a shielded container in the robot end effector so its performance is not affected by the presence of incident electromagnetic fields (see Fig. 4).

Figure 4. Isotropic E-field Probe

Figure 5. Photograph of the Probe and the Phantom

(See Section 6.2 for E-Probes Specifications)

## 4.1 E-FIELD PROBE CALIBRATION PROCESS

Each E-Probe/Probe amplifier combination has unique calibration parameters. A TEM calibration procedure is conducted to determine the proper amplifier settings to enter in the probe parameters. The amplifier settings are determined for a given frequency by subjecting the Probe to a known E-field density (1mW/cm<sup>2</sup>) using an RF Signal generator, TEM cell, and RF Power Meter. The SAR measurement software is used for Probe calibration (see Fig. 6).

Calibration is performed in two steps:

The free space E-field from amplified probe outputs is determined in a test chamber. This calibration can be performed in a TEM cell if the frequency is below 1 GHz and in a waveguide or some other methodologies above 1 GHz for free space. For the free space calibration, we place the probe in the volumetric center of the cavity and at the proper orientation with the field. We then rotate the probe 360 degrees until the three channels show the maximum reading. The power density readings equates to 1mW/cm<sup>2</sup>.

E-field temperature correlation calibration is performed in a flat phantom filled with the appropriate simulated brain tissue. The measured free space E-field in the medium correlates to temperature rise in a dielectric medium.

For temperature correlation calibration, a RF transparent thermistor-based temperature probe is used in conjunction with the E-field probe. The location of the maximum E-field close to the phantom's bottom is determined as a function of power into the RF source; in this case, a dipole. The E-field probe is moved sideways so that the temperature probe, while affixed to the E-field probe, is placed at the previous location of power levels used for the E-field measurement are recorded. The following equation related SAR to initial temperature slope :

$$SAR = C \frac{\Delta T}{\Delta t} \quad \text{where:}$$

$\Delta t$  = exposure time (30 seconds),

$C$  = heat capacity of tissue (brain or muscle),

$\Delta T$  = temperature increase due to RF exposure.

SAR is proportional to  $\Delta T / \Delta t$ , the initial rate of tissue heating, before thermal diffusion takes place.

Now it's possible to quantify the electric field in the simulated tissue by equating the thermally derived SAR to the E-field;

$$SAR = \frac{|E|^2 \cdot \sigma}{P} \quad \text{where:}$$

$\sigma$  = simulated tissue conductivity,

$P$  = Tissue density (1.25 g/cm<sup>3</sup> for brain tissue)

Figure 6. Probe Calibration Data in ViewField Window

The probe offset is determined by measuring the distance between the center of the sensor to the end of the protective tube. The data is collected when the probe outer surface make contact with the surface of the phantom and measures the corresponding field in the simulated tissue near the shell surface. An average slope is obtained from these data points nearest the surface and is used to define an exponential decay of the energy density with the depth.

The field attenuation versus depth is recorded and extrapolated to obtain the  $|E|^2$  value at the surface of the phantom where the maximum SAR is located.

$$\text{Slope} = \frac{\frac{E_{\text{total}} \cdot Z_1}{E_{\text{total}} \cdot Z_2} + \frac{E_{\text{total}} \cdot Z_2}{E_{\text{total}} \cdot Z_3}}{2}$$

$$\text{exp} = \ln(\text{slope}) \frac{\text{offset}}{\text{spacing}}$$

$$E_{\text{total}} \cdot Z_0 = E_{\text{total}} \cdot Z_1 \cdot e^{\text{exp}}$$

The 1 cm. voltage ( $E_{\text{total}} 1 \text{ cm}$ ) above the phantom's surface is needed to calculate the exposure of one gram of tissue. The SAR value (mW/g) estimates the average over a one gram cube obtained from the extrapolated value ( $E_{\text{total}} Z_0$ ) and interpolated value ( $E_{\text{total}} 1 \text{ cm}$ ) obtained by interpolation as shown below.

$$\text{SAR}(mW / g) = \frac{E_{\text{total}} \cdot Z_0 + E_{\text{total}} 1 \text{ cm}}{2} \cdot \frac{CF}{\text{SensorFactor}}$$

$$\text{SensorFactor} = \frac{10.8 \text{ mV}}{mW / cm^2} = \frac{0.0108V}{mW / cm^2}$$

$$\text{Conversion Factor (CF)} = \text{intermediate scaling constant for a particular probe which produced an output of } 10.8 \text{ mV in the TEM cell when the flux density is } 1 \text{ mW/cm}^2$$

## 5.1 PHANTOM AND THE BRAIN EQUIVALENT TISSUE

The phantom is an anatomically-shaped homogeneous torso model filled with a liquid simulating brain tissue. The phantom is placed at 0 degrees (horizontal position) with the left/right ear placed on the EUT (see Fig. 5). The phantom is made of a shell of fiberglass 1.5mm. thick (giving the worst case SAR value absorbed by brain tissue and the skull bones) and the EUT supported by a non-metallic (delrin) material\*. Similar phantoms have been used to simulate human head modelling studies[6][7].

The brain mixture consist of a viscous gel using hydroxethylcellulose (HEC) gelling agent and saline solution (see Table 1). Preservation with a bacteriacide is added and visual inspection is made to make sure air bubbles are not trapped during the mixing process. The mixture is calibrated to obtain proper dielectric constant (permittivity) and conductivity of the brain. The mixture characterizations used for the brain tissue simulating liquid are according to the data by C. Gabriel and G. Hartsgrrove [9].

BRAIN MIXTURE %	FREQUENCY 800 - 850 MHz	FREQUENCY 1850 -1910 MHz
WATER	40.4	45.0
SUGAR	56.0	53.9
SALT	2.5	0.0
BACTERIACIDE	0.1	0.1
HEC	1.0	1.0

Table 1. Composition of the Brain Tissue Equivalent Matter

\* Note: A simulating human hand is not used due to the complex anatomical and geometrical structure of the hand that may produced infinite number of configurations [8]. To produce the worst-case condition (the hand absorbs antenna output power), the hand is omitted during the tests.

## 6.1 SYSTEM SPECIFICATIONS

---

### Specifications

**POSITIONER:** IDX Robot with 6 axis  
**Repeatability:** 0.002 in.  
**Accuracy:** 0.004 in.

### Data Acquisition

**Processor:** Pentium PRO CPU  
**Clock Speed:** 200 MHz  
**Operating System:** Windows NT  
**Data Card:** National Instruments Analog Card  
**Software:** IDX Flexware  
**AMPLIFIER GAIN:** Adjustable 20 - 40, high isolation between channels  
**Connecting Lines:** High Impedance 4.5 kohm/foot  
**Sample Rate:** 6000

### E-Field Probe

**Probe Offset:** 2.5 mm  
**Frequency Band:** 150 - 2200 MHz  
**Conversion Factor:** 0.601 (800-880MHz)  
**Conversion Factor:** 1.20 (1850-1910MHz)  
**Dynamic Response:** 2  $\mu$ W/g - 10 mW/g  
**Input:** 2.2 meg  
**Isotropy:**  $\pm 0.5$  dB  
**Resolution:** 0.1 cm<sup>3</sup>

1.26

## 7.1 MEASUREMENT PROCESS

The measurement process consists of the process parameters, probe parameters, EUT product data, and measurement scans (teach points). The measurement process is a set of predefined points to be scanned and measured by the probe, DC amplified and process by the cell controller. The corresponding voltages determined by the electric and magnetic fields are extrapolated to determine peak SAR value.

The SAR Measurement System measures field strength by employing three different types of systematic measurement scans; an Area scan, a Zoom scan, and an SAR scan. Area and Zoom scans measure field strength in a rectangular area within the XY plane (a plane parallel to the top of the Robot Table). The measurement area is divided into a grid of small squares defined by equally-spaced grid lines. During an actual measurement process, the probe moves along grid lines systematically recording the field strength at grid line intersections. Typically, after an Area scan is completed, a Zoom scan is conducted at the peak field strength value (hot spots) that was measured in the Area scan. The Zoom scan usually has a greater resolution (smaller grid squares) than the Area scan, and covers only a fraction of the measurement area in the Area scan (see Fig. 7).

Figure 7. SAR Measurement Points in Area Scan and Zoom Scan Grids  
 Showing the Typical Hot Spot with respect to the Phone

## 8.1 TEST POSITION OF THE PHONE

Figure 8. Diagram showing Typical Alignment & Contact Points

The device was placed in a normal operating position with the center of its ear-piece aligned with the location of the ear canal on the phantom (See Fig. 9). With the ear-piece pressed against the head, the vertical center line of the body of the handset was aligned with an imaginary plane consisting of the three lines joining both ears and the tip of the mouth. While maintaining these alignments, the body of the handset was gradually moved towards the cheek until any point on the mouth-piece or keypad contacted the cheek (See Fig 8).

An upper right-hand corner antenna requires the left-hand phantom while handsets with an upper left antenna requires the right-hand phantom. The handset was tested both with its antenna extended (out) and retracted (in). A sample diagram of a typical handset shows the earpiece at the center of the X and Y axis, placed at the center of the ear canal of the phantom (see Fig. 10).

Figure 9. Sample of Handset alignment with the Ear Canal of the Phantom

Figure 10. Origin of Axis at Earpiece Position

## 9.1 ANSI/IEEE C95.1 - 1992 RF EXPOSURE LIMITS

HUMAN EXPOSURE	UNCONTROLLED ENVIRONMENT General Population (W/kg) or (mW/g)	CONTROLLED ENVIRONMENT Occupational (W/kg) or (mW/g)
SPATIAL PEAK SAR * (Brain)	1.60	8.00
SPATIAL AVERAGE SAR ** (Whole Body)	0.08	0.40
SPATIAL PEAK SAR *** (Hands / Feet / Ankle / Wrist)	4.00	20.00

Table 2. Safety Limits for Partial Body Exposure [2]

**NOTES:**

- \* The Spatial Peak value of the SAR averaged over any 1 gram of tissue (defined as a tissue volume in the shape of a cube) and over the appropriate averaging time.
- \*\* The Spatial Average value of the SAR averaged over the whole-body.
- \*\*\* The Spatial Peak value of the SAR averaged over any 10 grams of tissue (defined as a tissue volume in the shape of a cube) and over the appropriate averaging time.

**Uncontrolled Environments** are defined as locations where there is the exposure of individuals who have no knowledge or control of their exposure.

**Controlled Environments** are defined as locations where there is exposure that may be incurred by persons who are aware of the potential for exposure, (i.e. as a result of employment or occupation).

## 10.1 MEASUREMENT UNCERTAINTIES

---

Measurement uncertainties in SAR measurements are difficult to quantify due to several variables including biological, physiological, and environmental. However, we estimate the measurement uncertainties in SAR to be less than 15-25 %.

According to ANSI/IEEE C95.3, the overall uncertainty are difficult to assess and will vary with the type of meter and usage situation. However, accuracies of  $\pm 1$  to 3 dB can be expected in practice, with greater uncertainties in near-field situations and at higher frequencies (shorter wavelengths), or areas where large reflecting objects are present. Under optimum measurement conditions, SAR measurement uncertainties of at least  $\pm 2$  dB can be expected.[3]

According to CENELEC [5], typical worst-case uncertainty of field measurements is  $\pm 5$  dB. For well defined modulation characteristics the uncertainty can be reduced to  $\pm 3$  dB.

Estimated Errors	Percent
Measurement of the Conductivity/Dielectric Constant of the Tissue Simulant	$\pm 5$ %
Temperature Rise Calibration of Probe	$\pm 5$ %
Measurement of Thermal Capacity of Tissue Simulant	$\pm 5$ %
Accuracy of a Repeatable Phone Position	$\pm 10$ %
Probe Isotropic Response	$\pm 12$ %
Total Root-Sum Square Calculation	$\pm 17.9$ %

Table 3. Breakdown of Individual Errors

## 11.1 TEST DATA SUMMARY

Ambient TEMPERATURE (°C) 23.5  
Relative HUMIDITY (%) 58  
Atmospheric PRESSURE (kPa) 92

**NOTE:**

The E-field probe was calibrated by IDX Systems, Inc. The SAR calibration of the E-field probe is performed by temperature measurement procedure. A TEM cell is used for the free space calibration of the probe. The brain simulating material is calibrated by PCTEST using the dielectric probe system and network analyzer to determine the conductivity and permittivity (dielectric constant) of the brain-equivalent material.

The following list of equipment was used to calibrate the system (from IDX):

Power Meter	HP-437B
RF Generator	HP-8657B
Power Amp	Power System Technology (Amplifier Research)
TEM cell	IFI CC-110
Network Analyzer	HP-8753C

## 13.1 CONCLUSION

---

The SAR measurement indicates that the EUT complies with the RF radiation exposure limits of the FCC. These measurements are taken to simulate the RF effects exposure under worst-case conditions. Precise laboratory measures were taken to assure repeatability of the tests.

Please note that the absorption and distribution of electromagnetic energy in the body are very complex phenomena that depend on the mass, shape, and size of the body, the orientation of the body with respect to the field vectors, and the electrical properties of both the body and the environment. Other variables that may play a substantial role in possible biological effects are those that characterize the environment (e.g. ambient temperature, air velocity, relative humidity, and body insulation) and those that characterize the individual (e.g. age, gender, activity level, debilitation, or disease). Because innumerable factors may interact to determine the specific biological outcome of an exposure to electromagnetic fields, any protection guide shall consider maximal amplification of biological effects as a result of field-body interactions, environmental conditions, and physiological variables.[3]

Probe Name : PCTEST  
Field Type : E Field  
Orientation : 0 Degrees

Mixture Type = Brain  
Mixture Dielectric Constant = 43.400  
Mixture Conductivity = 0.900

Comment :  
CHAN 383 DUAL MODE PHONE  
CDMA MODE  
PCTEST SAR Measurement Laboratory

Robot : PCTEST

Probe Offset = 0.25 cm  
Sensor Factor = 0.0108  
Conversion Factor = 0.790

PCTEST Amplifier Channel Settings : 0.168 0.136 0.132

Diode Coefficients:  
Channel 1 An=-10.851 Bn=86.223 Cn=38.593 Dn=-0.016 Mn=0.026 Yn=0.000  
Channel 2 An=-21.618 Bn=92.335 Cn=34.909 Dn=-0.019 Mn=0.029 Yn=0.000  
Channel 3 An=-11.171 Bn=50.619 Cn=19.002 Dn=-0.025 Mn=0.052 Yn=0.001

Max Location : X = 6.500, Y = -0.500, Z = 0.000 (cm) Value = 12.372

Measured Values (volts) =  
1.279E-002 7.278E-003 3.775E-003 1.836E-003 5.183E-004 -5.563E-004  
-9.488E-004 -1.104E-003 -6.612E-004 -8.336E-004 -1.194E-003

Calc. Voltage @ Surface (Vs) = 0.0149

Voltage @ 1.00 cm (Vt) = 0.0087

Ave. Voltage (Vs+Vt)/2 = 0.0118

Ave. SAR over 1 g (mW/g) = 0.8619

Radio Type : OKI  
Model Number : UM9106  
Serial Number : 0008  
Frequency : 836.49 MHz  
Peak Trans. Pwr : 0.320 W  
Start Trans. Pwr: 0.320 W  
Antenna Type : Helical  
Antenna Posn. : Out  
Phantom Type : Head  
Phantom Posn. : Left Ear  
Scan Type : ZOOM/SAR  
Probe Name : PCTEST  
Field Type : E Field  
Orientation : 0 Degrees
