

6030-TX

Device Operation -

The 6030 PIR Transmitter, when activated by the PIR detecting motion, transmits a modulated code. This code consists of a device address configured via DIP Switches and a 'device state' setting determined by the 6030 when motion is detected. The transmitter sends an 'ON' state when motion is detected and 'OFF' state after the amount of time has passed that the user selects. When a receiving device is programmed via jumpers to the same code as the transmitter, receives this code it then adjusts its output according the 'device state' portion of the code (on, off).
