## Additional MPE exhibit for Teltest Report 2251 RF Exposure Calculations for FCC ID:CASTBA-H0

## Antenna type:

The antennas normally used with $400-520 \mathrm{MHz}$ UHF paging transmitters are vertically polarised collinear types with a typical length of 1.5 m , and a gain of $5 \mathrm{dBi}^{1}$. MPE calculations for lower end of the band (where the MPE limit is lowest) are given below.

Safe Distance Calculations at 400 MHz for 1.5 metre 5 dBi antenna ${ }^{1}$ :
Using Tell's near field equation ${ }^{2}$ :
Eq 1: $\quad S=$ Pnet $/(2 \pi R h)$
Re arrange to solve for R :

Eq 2: $\quad R=$ Pnet $/(2 \pi S h)$
For uncontrolled environment $S=\mathrm{f} / 1500 \mathrm{~mW}$ per $\mathrm{cm}^{2}$

$$
\mathrm{S}=0.267 \mathrm{~mW} \text { per } \mathrm{cm}^{2}
$$

For 100 watts:

$$
\begin{aligned}
& \mathrm{R}=100 \times 1000 /(2 \pi \times 0.267 \times 150) \\
& \mathrm{R}=398 \mathrm{~cm}
\end{aligned}
$$

Using the standard far field equation ${ }^{3}$ :

Eq 3: $\quad S=P G / 4 \pi R^{2}$
Re-arrange to solve for R :
Eq 4: $\quad R=\sqrt{ }(P G / 4 \pi S)$
For uncontrolled environment $S=\mathrm{f} / 1500 \mathrm{~mW}$ per $\mathrm{cm}^{2}$

$$
\begin{aligned}
& \mathrm{S}=0.267 \mathrm{~mW} \text { per } \mathrm{cm}^{2} \\
& \mathrm{R}=\sqrt{ }(100 \times 1000 \times 3.16) /(4 \pi \times 0.267) \\
& \mathrm{R}=307 \mathrm{~cm}
\end{aligned}
$$

Where:
$\mathrm{S}=$ power density in mW per $\mathrm{cm}^{2}$
P, Pnet = net power input to the antenna in mW
$\mathrm{R}=$ distance from the antenna in cm
$\mathrm{h}=$ aperture height of the antenna in cm
$\mathrm{G}=$ linear gain of antenna relative to an isotropic radiator
$\mathrm{f}=$ transmitter frequency in MHz

## Far field boundary calculations:

## Calculating the far field boundary distance ${ }^{4}$ :

Tell's equation applies for several metres from the antenna ${ }^{3}$, but may over predict the power density at longer distances. To determine which result should be used, plots of power density using Tell's and the conventional far field equations are plotted. The crossover point shows the transition between near cand far field regions. In the plot below, the transition occurs at about 235 cms . Hence the result for the far field calculation applies in this case.

## Conclusion:

The safe distance for the uncontrolled environment limit of 0.267 mW per $\mathrm{cm}^{2}$ was calculated using Tell's near field equation ( 3.98 m ) and the standard far field equation $(3.1 \mathrm{~m})$. To determine which result applies, power densities in the range 1 to 4 metres were plotted for both methods. The crossover point was used to determine the transition point from near field to far field. This point was about 2.35 metres from the antenna. Since both Tell's and far field equations gave results in the far field for a power density of 0.267 mW per sq cm , the applicable result was the far field distance, 3.1 m .

| Field Region | Distance | Tells Equation | Far Field Equation |
| :---: | :---: | :---: | :---: |
| Near Field | $0-2.35$ metres | Applies | Does not apply |
| Far Field | $>2.35$ metres | Does not apply | Applies |

This result shows that the FCC MPE requirements for the product are met provided users obey the instructions supplied, which recommend maintaining a minimum safe distance of 3.1 metres from the antenna.

## Information relating to Maximum Permissible Exposure Safe Distances:

Table of Safe Distances for representative Collinear Antennas:

| Transmitter Power 100 watts |  |  |
| :---: | :---: | :---: |
| Antenna <br> Gain dBi | Antenna <br> length in cm | Safe Distance in metres for <br> Uncontrolled Environment |
| 5 | 150 | 3.1 |
