Maximum Permissible Exposure calculations

The MPE distance will be calculated for the worst case of a 100% transmitter duty cycle. For an isotropic radiator the surface area of a sphere can be used to determine the area over which the transceiver energy is radiated.

Surface area of a sphere = $4 * \pi * radius_2$

In the case where there is an antenna gain, the worst case energy density is increased by the antenna gain. In this case, the exposure level for a controlled environment can be calculated as follows:

MPE distance =((output power*duty cycle*10*(antenna gain/10))/($4*\pi*Exposure Limit [mW/cm2]$))_{1/2}

In the case of 14 dBi HA8089 antenna

MPE distance = $((100 \text{ mW} * 1 * 25.1) / (4 * 3.14 * 1))_{1/2}$ = 22.7 cm

In the case of 6.5 dBi shark fin antenna

 $MPE \ distance = ((100 \ mW * 1 * 4.5) / (4 * 3.14 * 1))_{1/2} = 9.6 \ cm$
