1.2 <u>SUMMARY</u>

The unit supplied for testing is an Intermec Technologies Pocket PC Model 730, which offers 2.4GHz 802.11b Wireless LAN and Bluetooth connectivity.

The terminal utilizes the ActionTec 802CF13 Compact Flash 802.11b RLAN radio card and the ActionTec Bluetooth module.

SAR testing was performed at both the left and right ear of the phantom at both handset positions stated in the test specification. Testing was performed at the middle frequency and at the top and the bottom frequencies for the position giving maximum SAR. The sequence used accorded with the block diagram of tests given in EN 50361; OET65 (c) and IEEE1528. Testing was performed at maximum power of the device (17.5dBm). This was achieved using Client supplied Software.

SAR testing also performed with the device set in CW Mode placed against a Flat Phantom dimensions 220mmx200mmx150mm and with a sidewall thickness of 2.0mm. The phantom was filled to a depth of 150mm with 2450MHz Body simulant liquid. The dielectric properties were in accordance with the requirements for the dielectric properties specified in Supplement C (Edition 01-01) to OET Bulletin 65 (Edition 97-01).

SAR testing was carried out at the top, middle and bottom frequency of each of the device operating bands. The device was placed against the side of the flat phantom and was in contact, to simulate the worst-case position.

Intermec Technologies Pocket PC Model 730 had an integral antenna so that the requirement for testing with antenna extended and retracted was not applicable. The testing was performed with a fully charged battery for the positions for which higher SAR levels were recorded.

The device was then placed into the RLAN mode using onboard software supplied by the client, which enabled the device to be placed into a CW test mode. The channels 1, 6, 11 & 13 were selected in turn and the maximum SAR levels recorded

The Bluetooth module is a Class 2 device, max 2.5 dBm power output. No SAR scans for the Bluetooth module are included in this report.

Co-Location, this unit is designed to operate in co-located mode; with the RLAN radio Module and the Bluetooth module operating simultaneously. No SAR scans were carried out with the unit in this mode due to no SAR values were recorded above Noise floor levels for the Bluetooth module.

Note: for Body worn operation, the Intermec Technologies Pocket PC Model 730 is a Portable Data Terminal has been tested and meets the FCC RF exposure guidelines when used with an accessory which contains no metal and that positions these devices a minimum of 0.0cm from the body. Use of other accessories may not ensure compliance with FCC RF guidelines.

Included in this report are descriptions of the test method; the equipment used and an analysis of the test uncertainties applicable and diagrams indicating the locations of maximum SAR for each test position along with photographs indicating the positioning of the handset against either the right or left ear, as appropriate,

The maximum 10g volume averaged SAR level measured for all the tests performed did not exceed the 2 W/kg level defined for limiting the exposure of the general population to time-varying electric and magnetic fields by ICNIRP (1998), which is the relevant Standard for testing according to the CENELEC EN50361 test method.

The maximum 1g volume averaged SAR level measured for all the tests performed did not exceed the limits for General Population/Uncontrolled Exposure (W/kg) Partial Body of 1.6 W/kg. Level defined in Supplement C (Edition 01-01) to OET Bulletin 65 (97-01).

1.3 <u>TEST RESULT SUMMARY</u>

SYSTEM PERFORMANCE / VALIDATION CHECK RESULTS

Prior to formal testing being performed a System Check was performed in accordance with Appendix D IEEE1528 December 29, 2002 Draft Standard. The following results were obtained: -

Dipole Used	Frequency	Max 1g SAR	Percentage Drift on	Max 10g SAR	Percentage Drift on
	(MHz)	(W/kg)*	1g Reference	(W/kg)*	10g Reference
2450	2450	51.71*	-1.31%	23.94*	-0.25%

*Normalised to 1W

OUTPUT POWER OF TEST DEVICE MEASUREMENT METHOD

For the Intermec Technologies Corporation Pocket PC Model 730

The Spectrum Analyser was tuned to the test frequency. The device Output power setting was controlled via the 'Test Mode' on each handset being set to the conditions specified in the Summary on page 5 of this document. The device was then rotated through 360 degrees until the highest power level was observed in both planes of polarisation. The device was then replaced with a substitution antenna, the signal to the antenna was adjusted to equal the related level detected from the device.

MAXIMUM POWER

Recorded from the Intermec Technologies Corporation Pocket PC Model 730

Radio Device	Frequency (MHz)	Raw Result (dBm)	Substitution Level (dBm)	Cable Loss (dB)	Substitution Antenna Gain (dBi)	Result EIRP (dBm)	Result EIRP (mW)
RLAN	2412	-28.3	+6.7	Note 1	+9.0	+19.8*	95.5
RLAN	2437	-28.0	+7.1	Note 1	+9.0	+20.2*	104.7
RLAN	2462	-28.4	+7.3	Note 1	+9.0	+20.4*	109.6
Bluetooth	2402	-51.9	-18.3	Note 1	+9.2	-8.8	0.13
Bluetooth	2441	-48.0	-14.5	Note 1	+9.3	-5.2	0.30
Bluetooth	2480	-45.9	-11.9	Note 1	+9.3	-2.6	0.55

* - See Note 2

Note 1: Cable loss was ignored as the signal level was measured at the input to the horn antenna.

Note 2: A correction factor of 4.1dB has been applied to arrive at the final EIPR result. This is the difference between the measurements on the test receiver in a 1MHz bandwidth and a wideband power meter, to overcome the measuring receiver and detector limitations.

1.3 TEST RESULT SUMMARY - Continued

MAXIMUM SAR VALUES

The following is a summary of the maximum SAR values found during the assessment.

DSSS 2450 MHz Specific Absorption Rate (Maximum SAR) 1g & 10g RLAN Results for Intermec Technologies Corporation Pocket PC Model 730 placed against SAM Phantom (Head SAR)

Position	Channel Number	Frequency (MHz)	Max Spot (W/kg)	Max 1g SAR (W/kg)	Max 10g SAR (W/kg)	Area scan (Figure number)		
Right-Hand Side 15 Degrees	11	2462	1.05	0.832	0.446	Figure 23		
Limit for General Population (Uncontrolled Exposure) 1.6 W/kg (1g) & 2.0 W/kg (10g)								

DSSS 2450 MHz Specific Absorption Rate (Maximum SAR) 1g & 10g RLAN Results for Intermec Technologies Corporation Pocket PC Model 730 using an 'Industry Standard' Headset placed against SAM Phantom (Head SAR)

* Verified at time of test.

2.2 <u>TEST SOFTWARE</u>

The following software was used to control the BABT SARA2 System:

INSTRUMENT	VERSION NO.	DATE
SARA2 system	v.0.281	023/07/2002
Mitsubishi robot controller firmware revision	RV-E2 Version C9a	-
IXA-10 Probe amplifier	Version 2.5	-

2.3 DIELECTRIC PROPERTIES OF SIMULANT LIQUIDS

The dielectric properties of the tissue simulant liquids used for the SAR testing at BABT are as follows:-

FLUID TYPE AND FREQUENY	RELATIVE PERMITTIVITY εr (ε') TARGET	RELATIVE PERMITTIVITY εr (ε') MEASURED	CONDUCTIVITY σ TARGET	CONDUCTIVITY σ MEASURED
Head 2450MHz	39.2	36.90	1.80 S/m	1.877
Body 2450MHz	52.7	51.40	1.95 S/m	2.011

Fluid Mass Density, $\rho = 1000 \text{ kg/m}^3$

The fluids were calibrated in our Laboratory and re-checked prior to any measurements being made against reference fluids stated in IEEE 1528-200X of 0.9% NaCl (Salt Solution) at 20°C and also for Dimethylsulphoxide (DMS) at 20°C.

The fluids were made at BABT under controlled conditions from the following OET(65)c formulae and reference made to Draft Standard IEEE1528-200x. The composition of ingredients may have been modified accordingly to achieve the desired target tissue parameters required for routine SAR evaluation:

Ingredients	Frequency (MHz)									
(% by weight)	4	50	83	35	915		1900		2450	
Tissue Type	Head	Body	Head	Body	Head	Body	Head	Body	Head	Body
Water	38.56	51.16	41.45	52.4	41.05	56.0	54.9	40.4	62.7	73.2
Salt (NaCl)	3.95	1.49	1.45	1.4	1.35	0.76	0.18	0.5	0.5	0.04
Sugar	56.32	46.78	56.0	45.0	56.5	41.76	0.0	58.0	0.0	0.0
HEC	0.98	0.52	1.0	1.0	1.0	1.21	0.0	1.0	0.0	0.0
Bactericide	0.19	0.05	0.1	0.1	0.1	0.27	0.0	0.1	0.0	0.0
Triton X-100	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	36.8	0.0
DGBE	0.0	0.0	0.0	0.0	0.0	0.0	44.92	0.0	0.0	26.7
Dielectric Constant	43.42	58.0	42.54	56.1	42.0	56.8	39.9	54.0	39.8	52.5
Conductivity (S/m)	0.85	0.83	0.91	0.95	1.0	1.07	1.42	1.45	1.88	1.78

2.4 TEST CONDITIONS

Ambient Temperature: Within +15°C to +35°C at 20% RH to 75% RH. The actual Temperature during the testing ranged from 21.9°C to 23.8°C. The actual Humidity during the testing ranged from 21.8% to 25.9% RH.

Tissue simulating liquid temperature: +20°C to +25°C.

The actual tissue simulating liquid temperature was recorded as min 22.0°C and max 22.8°C SAR Drift in during scans. The maximum SAR Drift, drift due to the mobile phone electronics, was recorded as -2.120 all of the testing.

2.5 MEASUREMENT UNCERTAINTY

ROBOT SYSTEM SPECIFICATION

The SAR measurement system being used is the IndexSAR SARA2 system, which consists of a Mitsubishi RV-E2 6-axis robot arm and controller, IndexSAR probe and amplifier and SAM phantom Head Shape. The robot is used to articulate the probe to programmed positions inside the phantom head to obtain the SAR readings from the DUT.

The system is controlled remotely from a PC, which contains the software to control the robot and data acquisition equipment. The software also displays the data obtained from test scans.

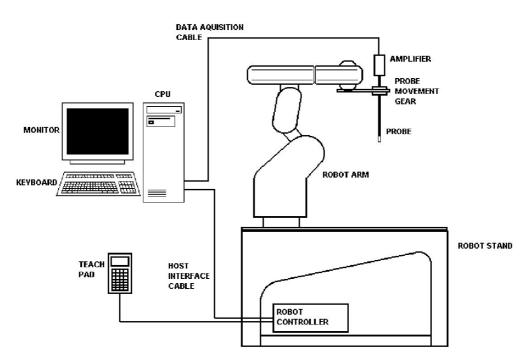

Figure 1: Schematic diagram of the SAR measurement system

The position and digitised shape of the phantom heads are made available to the software for accurate positioning of the probe and reduction of set-up time. The SAM phantom heads are individually digitised using a Mitutoyo CMM machine to a precision of 0.001mm. The data is then converted into a shape format for the software, providing an accurate description of the phantom shell.

In operation, the system first does an area (2D) scan at a fixed depth within the liquid from the inside wall of the phantom. When the maximum SAR point has been found, the system will then carry out a 3D scan centred at that point to determine volume averaged SAR level.

PROBE AND AMPLIFIER SPECIFICATION

IXP-050 Indexsar isotropic immersible SAR probe

The probes are constructed using three orthogonal dipole sensors arranged on an interlocking, triangular prism core. The probes have built-in shielding against static charges and are contained within a PEEK cylindrical enclosure material at the tip. Probe calibration is described in the following section.

IXP-039 Amplifier

The amplifier unit has a multi-pole connector to connect to the probe and a multiplexer selects between the 3-channel single-ended inputs. A 16-bit AtoD converter with programmable gain is used along with an on-board micro-controller with non-volatile firmware. Battery life is around 150 hours and data are transferred to the PC via 3m of duplex optical fibre and a self-powered RS232 to optical converter.

Phantoms

The Specific Anthropomorphic Mannequin (SAM) Upright Phantom is fabricated using moulds generated from the CAD files as specified by CENELEC EN50361. It is mounted via a rotation base to a supporting table, which also holds the robotic positioner. The phantom and robot alignment is assured by both mechanical and laser registration systems.

PROBE CALIBRATION PROCEDURE

EQUIPMENT USED

For the first part of the characterisation procedure, the probe is placed in an isotropy measurement jig as pictured in Figure 2. In this position the probe can be rotated about its axis by a non-metallic belt driven by a stepper motor.

The probe is attached via its amplifier and an optical cable to a PC. A schematic representation of the test geometry is illustrated in Figure 3.

A balanced dipole (900 MHz) is inserted horizontally into the bracket attached to a second belt (Figure 2). The dipole can also be rotated about its axis. A cable connects the dipole to a signal generator, via a directional coupler and power meter. The signal generator feeds an RF amplifier at constant power, the output of which is monitored using the power meter. The probe is positioned so that its sensors line up with the rotation center of the source dipole. By recording output voltage measurements of each channel as both the probe and the dipole are rotated, data are obtained from which the spherical isotropy of the probe can be optimised and its magnitude determined.

The calibration process requires E-field measurements to be taken in air, in 900 MHz simulated brain liquid and at other frequencies/liquids as appropriate.

LINEARISING PROBE OUTPUT

The probe channel output signals are linearised in the manner set out in Refs [1] and [2]. The following equation is utilized for each channel:

$$U_{lin} = U_{o/p} + U_{o/p}^{2} / DCP$$
 (1)

where U_{lin} is the linearised signal, $U_{o/p}$ is the raw output signal in voltage units and DCP is the diode compression potential in similar voltage units.

DCP is determined from fitting equation (1) to measurements of U_{lin} versus source feed power over the full dynamic range of the probe. The DCP is a characteristic of the schottky diodes used as the sensors. For the IXP-050 probes with CW signals the DCP values are typically 0.10V (or 20 in the voltage units used by Indexsar software, which are V*200).

SELECTING CHANNEL SENSITIVITY FACTORS TO OPTIMISE ISOTROPIC RESPONSE

The basic measurements obtained using the calibration jig (Fig 2) represent the output from each diode sensor as a function of the presentation angle of the source (probe and dipole rotation angles). The directionality of the orthogonally-arranged sensors can be checked by analysing the data using dedicated Indexsar software, which displays the data in 3D format as in Figure 4. The left-hand side of this diagram shows the individual channel outputs after linearisation (see above). The program uses these data to balance the channel outputs and then applies an optimisation process, which makes fine adjustments to the channel factors for optimum isotropic response.

PROBE CALIBRATION PROCEDURE - Continued

The next stage of the process is to calibrate the Indexsar probe to a W&G EMR300 E-field meter in air. The principal reasons for this are to obtain conversion factors applicable should the probe be used in air and to provide an overall measure of the probe sensitivity.

A multiplier is applied to factors to bring the magnitudes of the average E-field measurements as close as possible to those of the W&G probe.

The following equation is used (where linearised output voltages are in units of V*200):

 $E_{air}^{2} (V/m) = U_{linx} * Air Factor_{x}$ $+ U_{liny} * Air Factor_{y}$ $+ U_{linz} * Air Factor_{z}$ (2)

It should be noted that the air factors are not separately used for normal SAR testing. The IXP-050 probes are optimised for use in tissue-simulating liquids and do not behave isotropically in air.

900 MHz LIQUID CALIBRATION

Conversion factors for use when the probes are immersed in tissue-simulant liquids at 900 MHz are determined either using a waveguide or by comparison to a reference probe that has been calibrated by NPL. Waveguide procedures are described later. The summary sheet indicates the method used for the probe S/N 0084.

The conversion factor, referred to as the 'liquid factor' is also applied to the measurements of each channel. The following equation is used (where output voltages are in units of V*200):

E_{lig}^{2} (V/m) =	U _{linx} * Air Factor _x * Liq Factor _x	
	+ U _{liny} * Air Factor _y * Liq Factor _y	
	+ U _{linz} * Air Factor _z * Liq Factor _z	(3)

A 3D representation of the spherical isotropy for probe S/N 0084 using these factors is shown in Figure 4

The rotational isotropy can also determined from the calibration jig measurements and is reported as the 900MHz isotropy in the summary table. Note that waveguide measurements can also be used to determine rotational isotropy (Fig. 6).

The design of the cells used for determining probe conversion factors are waveguide cells is shown in Figure 5. The cells consist of a coax to waveguide transition and an open-ended section of waveguide containing a dielectric separator. Each waveguide cell stands in the upright positition and is filled with liquid within 10 mm of the open end. The seperator provides a liquid seal and is designed for a good electrical transition from air filled guide to liquid filled guide. The choice of cell depends on the portion of the frequency band to be examined and the choice of liquid used. The depth of liquid ensures there is negligible radiation from the waveguide open top and that the probe calibration is not influenced by reflections from nearby objects. The return loss at the coaxial connector of the filled waveguide cell is measured initially using a network analyser and this information is used subsequently in the calibration procedure. The probe is positioned in the centre of the waveguide and is adjusted vertically or rotated using stepper motor arrangements. The signal generator is connected to the waveguide cell and the power is monitored with a coupler and a power meter. A fuller description of the waveguide method is given below.

PROBE CALIBRATION PROCEDURE - Continued

The liquid dielectric parameters used for the probe calibrations are listed in the Tables below. The final calibration factors for the probe are listed in the summary chart.

WAVEGUIDE MEASUREMENT PROCEDURE

The calibration method is based on setting up a calculable specific absorption rate (SAR) in a vertically-mounted WG8 (R22) waveguide section [1]. The waveguide has an air-filled, launcher section and a liquid-filled section separated by a matching window that is designed to minimise reflections at the liquid interface. A TE₀₁ mode is launched into the waveguide by means of a N-type-to-waveguide adapter. The power delivered to the liquid section is calculated from the forward power and reflection coefficient measured at the input to the waveguide. At the centre of the cross-section of the waveguide, the local spot SAR in the liquid as a function of distance from the window is given by functions set out in IEEE1528 as below:

Because of the low cutoff frequency, the field inside the liquid nearly propagates as a TEM wave. The depth of the medium (greater than three penetration depths) ensures that reflections at the upper surface of the liquid are negligible. The power absorbed in the liquid is determined by measuring the waveguide forward and reflected power. Equation (4) shows the relationship between the SAR at the cross-sectional center of the lossy waveguide and the longitudinal distance (*z*) from the dielectric separator

$$SAR(z) = \frac{4(P_f - P_b)}{\rho ab\delta} e^{-2z/\delta}$$
(4)

where the density ρ is conventionally assumed to be 1000 kg/m³, *ab* is the cross-sectional area of the waveguide, P_f and P_b are the forward and reflected power inside the lossless section of the waveguide, respectively. The penetration depth δ , which is the reciprocal of the waveguide-mode attenuation coefficient, is determined from a scan along the *z*-axis and compared with the theoretical value determined from Equation (5) using the measured dielectric properties of the lossy liquid.

$$\delta = \left[\operatorname{Re}\left\{ \sqrt{\left(\pi / a\right)^{2} + j\omega\mu_{o}\left(\sigma + j\omega\varepsilon_{o}\varepsilon_{r}\right)} \right\} \right]^{-1}$$
(5)

Table A.1 of [1] can be used for designing calibration waveguides with a return loss greater than 30 dB at the most important frequencies used for personal wireless communications. Values for the penetration depth for these specific fixtures and tissue-simulating mixtures are also listed in Table A.1.

According to [1], this calibration technique provides excellent accuracy, with standard uncertainty of less than 3.6% depending on the frequency and medium. The calibration itself is reduced to power measurements traceable to a standard calibration procedure. The practical limitation to the frequency band of 800 to 2500 MHz because of the waveguide size is not severe in the context of compliance testing.

PROBE CALIBRATION PROCEDURE - Continued

CALIBRATION FACTORS MEASURED FOR PROBE S/N 0084

The probe was calibrated at 900, 1800, 1900 and 2450MHz MHz in liquid samples representing both brain liquid and body fluid at these frequencies. The calibration was for CW signals only, and the axis of the probe was parallel to the direction of propagation of the incident field i.e. end-on to the incident radiation. The axial isotropy of the probe was measured by rotating the probe about its axis in 10 degree steps through 360 degrees in this orientation.

The reference point for the calibration is in the centre of the probe's cross-section at a distance of 2.7 m from the probe tip in the direction of the probe amplifier. A value of 2.7 mm should be used for the tip to sensor offset distance in the software.

It is important that the diode compression point and air factors used in the software are the same as those quoted in the results tables, as these are used to convert the diode output voltages to a SAR value.

DIELECTRIC PROPERTIES OF LIQUIDS

The dielectric properties of the brain and body tissue-simulant liquids employed for calibration are listed in the tables below. The measurements were performed prior to each waveguide test using an Indexsar DiLine measurement kit, which uses the TEM method as recommended in [2].

AMBIENT CONDITIONS

Measurements were made in the open laboratory at $22 \pm 2.0^{\circ}$ C. The temperature of the liquids in the waveguide used was measured using a mercury thermometer.

RESPONSE TO MODULATED SIGNALS

To measure the response of the probe and amplifier to modulated signals, the probe is held vertically in a liquid-filled waveguide.

An RF amplifier is allowed to warm up and stabilise before use. A spectrum analyser is used to demonstrate that the peak power of the RF amplifier for the CW signals and the pulsed signals are within 0.1dB of each other when the signal generator is switched from CW to modulated output. Subsequently, the power levels recorded are read from a power meter when a CW signal is being transmitted.

The test sequence involves manually stepping the power up in regular (e.g. 2 dB) steps from the lowest power that gives a measurable reading on the SAR probe up to the maximum that the amplifiers can deliver.

At each power level, the individual channel outputs from the SAR probe are recorded at CW and then recorded again with the modulation setting. The results are entered into a spreadsheet. Using the spreadsheets, the modulated power is calculated by applying a factor to the measured CW power (e.g. for GSM, this factor is 9.03dB). This process is repeated 3 times with the response maximised for each channel sensor in turn.

FCC ID: EHA-802CFI3

2.6 SAR MEASUREMENT SYSTEM

PROBE CALIBRATION PROCEDURE - Continued

The probe channel output signals are linearised in the manner set out in Section 1 above using equation (1) with the DCPs determined from the linearisation procedure. Calibration factors for the probe are used to determine the E-field values corresponding to the probe readings using equation (3). SAR is determined from the equation

SAR (W/kg) =
$$E_{lig}^{2}$$
 (V/m) * σ (S/m) / 1000 (6)

Where σ is the conductivity of the simulant liquid employed.

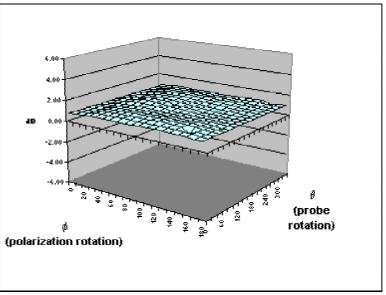

Using the spreadsheet data, the DCP value for linearising each of the individual channels (X, Y and Z) is assessed separately. The corresponding DCP values are listed in the summary page of the calibration factors for each probe.

Figure 9 shows the linearised probe response to 900MHz GSM signals, Figure 9a the response to 1800MHz GSM signals, Figure 10 the response to GPRS signals (GSM with 2 timeslots) and Figure 11 &12 the response to CDMA IS-95A and W-CDMA signals.

Additional tests have shown that the modulation response is similar at 1800MHz and is not affected by the orientation between the source and the probe.

PROBE SPECIFICATIONS

IndexSAR probe 0084, along with its calibration, is compared with CENELEC and IEEE standards recommendations (Refs [1] and [2]) in the Tables below. A listing of relevant specifications is contained in the tables below:

DIMENSIONS	S/N 0084	CENELEC [1]	IEEE [2]
Overall length (mm)	350		
Tip length (mm)	10		
Body diameter (mm)	12		
Tip diameter (mm)	5.2	8	8
Distance from probe tip to dipole centers (mm)	2.7		

DYNAMIC RANGE	S/N 0084	CENELEC [1]	IEEE [2]
Minimum (W/kg)	0.01	<0.02	0.01
Maximum (W/kg)	>100	>100	100

LINEARITY OF RESPONSE	S/N 0084	CENELEC [1]	IEEE [2]
	0.125	0.50	0.25
Over range 0.01 – 100 W/kg (+/- dB)			

Isotropy (measured at 900MHz)	S/N 0084	CENELEC [1]	IEEE [2]
Axial rotation with probe normal to source	Max. 0.13	0.5	0.25
(+/- dB) at 900, 1800, 1900 and 2450 MHz	(see summary table)		
Spherical isotropy covering all orientations to	0.34	1.0	0.50
source (+/- dB)			

CONSTRUCTION	Each probe contains three orthogonal dipole sensors arranged on a triangular prism core, protected against static charges by built-in shielding, and covered at the tip by PEEK cylindrical enclosure material. No adhesives are used in the immersed section. Outer case materials are PEEK and heat-shrink sleeving.
CHEMICAL RESISTANCE	Tested to be resistant to glycol and alcohol containing simulant liquids but probes should be removed, cleaned and dried when not in use.

SAR MEASUREMENT PROCEDURE

Figure 13: Principal components of the SAR measurement test bench

The major components of the test bench are shown in the picture above. A test set and dipole antenna control the handset via an air link and a low-mass phone holder can position the phone at either ear. Graduated scales are provided to set the phone in the 15 degree position. The upright phantom head holds approx. 7 litres of simulant liquid. The phantom is filled and emptied through a 45mm diameter penetration hole in the top of the head.

After an area scan has been done at a fixed distance of 8mm from the surface of the phantom on the source side, a 3D scan is set up around the location of the maximum spot SAR. First, a point within the scan area is visited by the probe and a SAR reading taken at the start of testing. At the end of testing, the probe is returned to the same point and a second reading is taken. Comparison between these start and end readings enables the power drift during measurement to be assessed.

SARA2 Interpolation and Extrapolation schemes

SARA2 software contains support for both 2D cubic B-spline interpolation as well as 3D cubic B-spline interpolation. In addition, for extrapolation purposes, a general n^{-th} order polynomial fitting routine is implemented following a singular value decomposition algorithm presented in [4]. A 4th order polynomial fit is used by default for data extrapolation, but a linear-logarithmic fitting function can be selected as an option. The polynomial fitting procedures have been tested by comparing the fitting coefficients generated by the SARA2 procedures with those obtained using the polynomial fit functions of Microsoft Excel when applied to the same test input data.

Interpolation of 2D area scan

The 2D cubic B-spline interpolation is used after the initial area scan at fixed distance from the phantom shell wall. The initial scan data are collected with approx. 10mm spatial resolution and spline interpolation is used to find the location of the local maximum to within a 1mm resolution for positioning the subsequent 3D scanning.

SAR MEASUREMENT PROCEDURE - Continued

Extrapolation of 3D scan

For the 3D scan, data are collected on a spatially regular 3D grid having (by default) 6.4 mm steps in the lateral dimensions and 3.5 mm steps in the depth direction (away from the source). SARA2 enables full control over the selection of alternative step sizes in all directions.

The digitised shape of the head is available to the SARA2 software, which decides which points in the 3D array are sufficiently well within the shell wall to be 'visited' by the SAR probe. After the data collection, the data are extrapolated in the depth direction to assign values to points in the 3D array closer to the shell wall. A notional extrapolation value is also assigned to the first point outside the shell wall so that subsequent interpolation schemes will be applicable right up to the shell wall boundary.

Interpolation of 3D scan and volume averaging

The procedure used for defining the shape of the volumes used for SAR averaging in the SARA2 software follow the method of adapting the surface of the 'cube' to conform with the curved inner surface of the phantom (see Appendix C.2.2.1 in EN 50361). This is called, here, the conformal scheme.

For each row of data in the depth direction, the data are extrapolated and interpolated to less than 1mm spacing and average values are calculated from the phantom surface for the row of data over distances corresponding to the requisite depth for 10g and 1g cubes. This results in two 2D arrays of data, which are then cubic B-spline interpolated to sub mm lateral resolution. A search routine then moves an averaging square around through the 2D array and records the maximum value of the corresponding 1g and 10g volume averages. For the definition of the surface in this procedure, the digitised position of the headshell surface is used for measurement in head-shaped phantoms. For measurements in rectangular, box phantoms, the distance between the phantom wall and the closest set of gridded data points is entered into the software.

For measurements in box-shaped phantoms, this distance is under the control of the user. The effective distance must be greater than 2.5mm as this is the tip-sensor distance and to avoid interface proximity effects, it should be at least 5mm. A value of 6 or 8mm is recommended. This distance is called **dbe** in EN 50361.

For automated measurements inside the head, the distance cannot be less than 2.5mm, which is the radius of the probe tip and to avoid interface proximity effects, a minimum clearance distance of x mm is retained. The actual value of dbe will vary from point to point depending upon how the spatially-regular 3D grid points fit within the shell. The greatest separation is when a grid point is just not visited due to the probe tip dimensions. In this case the distance could be as large as the step-size plus the minimum clearance distance (i.e with x=5 and a step size of 3.5, **dbe** will be between 3.5 and 8.5mm).

The default step size (**dstep** in EN 50361) used is 3.5mm, but this is under user-control. The compromise is with time of scan, so it is not practical to make it much smaller or scan times become long and power-drop influences become larger.

The robot positioning system specification for the repeatability of the positioning (**dss** in EN50361) is +/-0.04mm.

SAR MEASUREMENT PROCEDURE - Continued

The phantom shell is made by an industrial moulding process from the CAD files of the SAM shape, with both internal and external moulds. For the upright phantoms, the external shape is subsequently digitised on a Mitutoyo CMM machine (Euro C574) to a precision of 0.001mm. Wall thickness measurements made non-destructively with an ultrasonic sensor indicate that the shell thickness (**dph**) away from the ear is 2.0 +/- 0.1mm. The ultrasonic measurements were calibrated using additional mechanical measurements on available cut surfaces of the phantom shells.

For the upright phantom, the alignment is based upon registration of the rotation axis of the phantom on its 253mm-diameter baseplate bearing and the position of the probe axis when commanded to go to the axial position. A laser alignment tool is provided (procedure detailed elsewhere). This enables the registration of the phantom tip (**dmis**) to be assured to within approx. 0.2mm. This alignment is done with reference to the actual probe tip after installation and probe alignment. The rotational positioning of the phantom is variable – offering advantages for special studies, but locating pins ensure accurate repositioning at the principal positions (LH and RH ears).

2.7 EN50361 TEST POSITIONS

This recommended practice specifies exactly two test positions for the handset against the head phantom, the "cheek" position and the "tilted" position. These two test positions are defined in the following sub-clauses. The handset should be tested in both positions on the left and right sides of the SAM phantom. In each test position the centre of the earpiece of the device is placed directly at the entrance of the auditory canal. The angles mentioned in the test positions used are referenced to the line connecting both auditory canal openings. The plane this line is on is known as the reference plane. Testing is performed on the right and left-hand sides of the generic phantom head.

Figure 14. – Side View of Mobile next to head showing alignment.

The Cheek Position

The Cheek Position is where the mobile is in the reference plane and the line between the mobile and the line connecting both auditory canal openings is reduced until any part of the mobile touches any part of the generic twin phantom head.

The 15° Position

The 15° Position is where the mobile is in the reference cheek position and the phone is kept in contact with the auditory canal at the earpiece, the bottom of the phone is then tilted away from the phantom mouth by 15° .

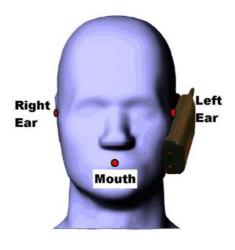

Figure 15. – Cheek Position.

Phantom S/No: 04/02 FT04 Phantom Rotation (deg): 0	Conductivity 2.001 Liquid Ambient 22.3 °C
Test Position 2.0mm Side Touch	Max SAR 'Y' Axis Location: 7.0 mm
Antenna Position : Integrated	Max SAR 'Z' Axis Location: -143.6 mm
Test Frequency: 2412 MHz	SAR 1g 0.840 W/kg
Modulation / Test Mode : CW	SAR 10g: 0.434 W/kg
Crest Factor: 1.0	SAR Drift: -0.106 dB
Diode Compression factor: 20;20;20	Probe Conversion Factors: 0.468

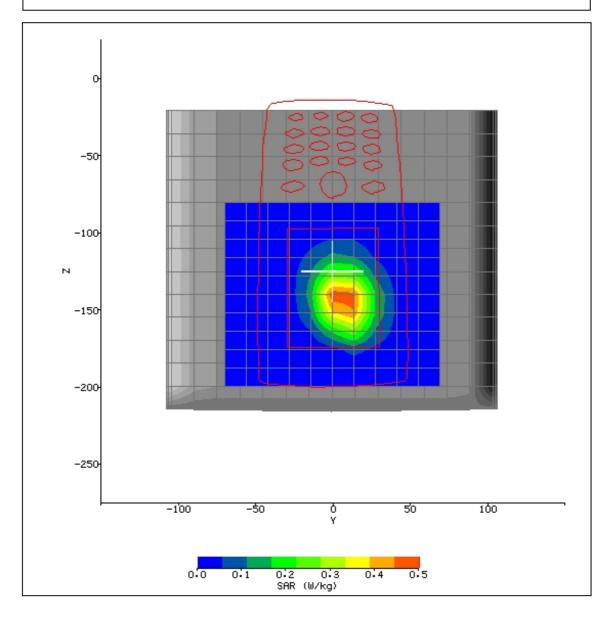

Figure 26

System : IndexSAR SARA2 Date of Test : 22/09/03 Lab Ambient : 22.8 °C Device ID : 730 Phantom : SAM Phantom S/No : 04/02 FT04	Power Drift
Phantom Rotation (deg): 0	Liquid Ambient: 22.3°C
Test Position 2.0mm Side Touch	Max SAR 'Y' Axis Location: 5.6 mm
Antenna Position: Integrated	Max SAR 'Z' Axis Location: -142.4 mm
Test Frequency : 2437 MHz	SAR 1g 0.856 W/kg
Modulation / Test Mode : CW	SAR 10g 0.440 W/kg
Crest Factor: 1.0	SAR Drift: -0.149 dB
Diode Compression factor : 20;20;20	Probe Conversion Factors: 0.468

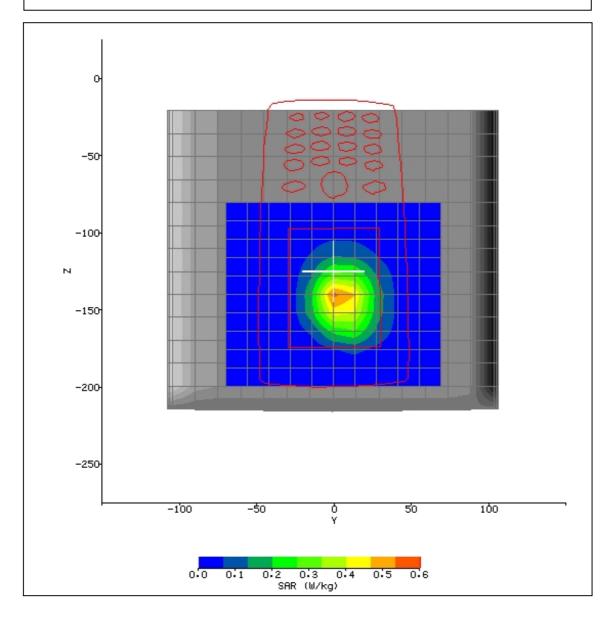

Figure 27

System : IndexSAR SARA2 Date of Test : 22/09/03 Lab Ambient : 22.0 °C Device ID : 730 Phantom : SAM	Power Drift: 0.0 dB Battery Model: 318-011-004 Probe Serial Number: IXP-050 0084 Liquid Simulant: 2450 MHz Body Permittivity
Phantom S/No: 04/02 FT04	Conductivity: 2.001
Phantom Rotation (deg): 0	Liquid Ambient 21.9 °C
Test Position 2.0mm Side Touch	Max SAR 'Y' Axis Location: 7.0 mm
Antenna Position: Integrated	Max SAR 'Z' Axis Location: -144.8 mm
Test Frequency: 2462 MHz	SAR 1g 0.828 W/kg
Modulation / Test Mode : CW	SAR 10g 0.429 W/kg
Crest Factor : 1.0	SAR Drift: -0.071 dB
Diode Compression factor: 20;20;20	Probe Conversion Factors: 0.468

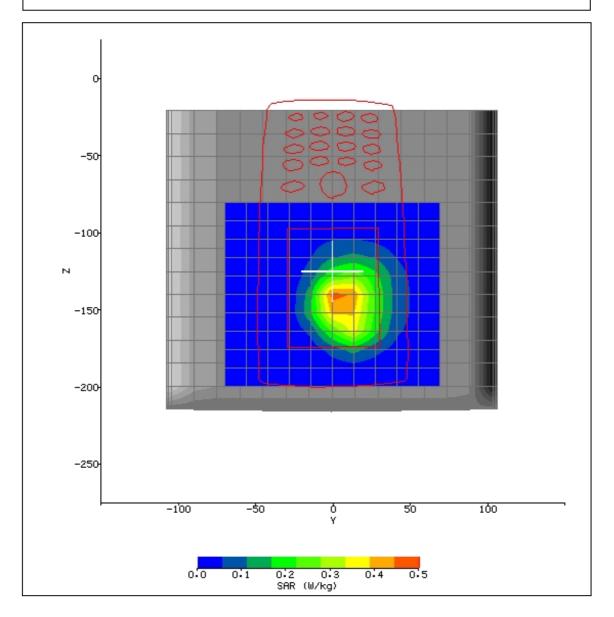

Figure 28

System : IndexSAR SARA2	Power Drift: 0.0 dB
Date of Test : 22/09/03	Battery Model: 318-011-004
Lab Ambient: 22.1°C	Probe Serial Number: IXP-050 0084
Device ID	Liquid Simulant: 2450 MHz Bodyl
Phantom : SAM	Permittivity: 51.40
Phantom S/No: 04/02 FT04	Conductivity: 2.011
Phantom Rotation (deg): 0	Liquid Ambient: 21.9 °C
Test Position : 2.0mm Side Touch	Max SAR 'Y' Axis Location: 7.0 mm
Antenna Position : Integrated	Max SAR 'Z' Axis Location: -148.4 mm
Test Frequency : 2472 MHz	SAR 1g: 0.703 W/kg
Modulation / Test Mode : CW	SAR 10g 0.365 W/kg
Crest Factor: 1.0	SAR Drift: 0.059 dB
Diode Compression factor : 20;20;20	Probe Conversion Factors: 0.468
