1.1 Measurement Uncertainty

Confidence Statement

The measurement uncertainty statements below use a Coverage Factor K = 2.
The Coverage Factor K = 2 equates to an approximate confidence level of 95%.

Receiver and Transmitter Direct Measurements Of Conducted Emissions Using HP8566B Spectrum Analyzer and HP85685A Preselector

   0-1.0 GHz has an Expanded Measurement Uncertainty of   +/- 2.36 dB.
   1.0-2.0 GHz has an Expanded Measurement Uncertainty of   +/- 3.50 dB.
   2.0-2.5 GHz has an Expanded Measurement Uncertainty of   +/- 0.85 dB.

Tektronix TDS460

   Amplitude Measurements Expanded Measurement Uncertainty, +/- 1.5% full scale
   Time Measurements Expanded Measurement Uncertainty, +/- 0.015%

2.0 REPORT REFERENCE:

   The ABTM3 radio module description is contained within reports from CKC
   Report No.: FC01-057 and is supplemented with Intermec Report No.: 577-500-988.

3.0 HYBRID MODE OPERATION

3.1 OPERATION DESCRIPTION

   See Appendix A for details of radio operation.

3.2 PROCESS GAIN

   The radio chip within the ABTM3 radio is manufactured by Cambridge Silicon Radio, Part Number BC01B. See Appendix B for the Process Gain Memorandum from CSR.

3.3 TRANSMITTER AVERAGE TIME OF CHANNEL OCCUPANCY

   An ABTM3 radio module is modified to direct connect the output of the transmitter to the measurement equipment. The output of the radio is 50 Ohms.
   Conditions during testing

   Temp: 22C, RH: 40%, BP: 29.8 inches

   Performed By: Dave Fry   Oct. 17, 2001

REPORT NO: 20011018-1
DATE: October 18, 2001
Page 5 of 12
FCC ID: EHAABTM3

Equipment Setup:

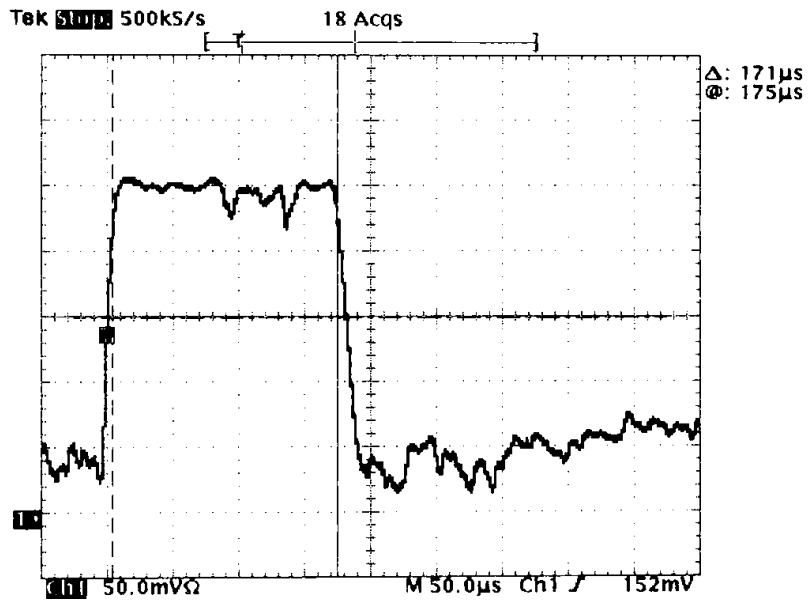

See section 4.0 for equipment list.

Test Procedure:
1) Prior to making conducted measurements of the transmitter, verify the cable losses and attenuation for conducted measurements in the frequency band of interest.

2) Connect the modified radio directly to the spectrum analyzer input using the calibrated cable and attenuator. Set the radio to "inquiry" mode and plot the transmitter channels in the permitted band. Use 100kHz resolution and video bandwidths.

3) Repeat for "page" mode operation.

4) To measure the narrow transmission widths accurately connect a digital storage oscilloscope (DSO) to the spectrum analyzer video out.

5) Set the spectrum analyzer on a center frequency of 2441 MHz (Ch. 40) of the transmitter. Using 0 Hz span with 100 kHz RBW and 100kHz VBW plot a 20 msec sweep while the transmitter is operating in inquiry mode in the above configuration. Print this plot that shows the transmission cycle.

6) While the radio continues to transmit use the DSO to show a similar plot at 2 mS/division. Using the cursors to mark the repetition rate and print this plot.

7) Make a second DSO plot that details the transmission time on channel.

8) Calculate the worst-case average transmitter average occupancy based on the plotted information presented.

Page mode number of hopping frequencies

Inquiry mode number of hopping frequencies
Results:

"Page" and "Inquiry" modes operate by first hopping with 16 channels. This "Train A" sequence repeats every 10 mS. Every 1.28 seconds hopping frequencies change and a second Train A starts using different frequencies resulting in 128 transmissions on a frequency or channel. After a maximum of seven "Train A" sequences of 1.28 seconds, 16 new hopping channels is selected, "Train B". If a same frequency is used in both Train A and B, the resulting worst case conditions occur. First 7 x 1.28 x 10mS, the next 7 sequences with Train B, then with other frequencies. Calculating the results below.

1st 128 events x 7 Train A sequences x 10mS = 8.96 seconds
2nd 128 events x 7 Train B sequences x 10mS = 8.96 seconds
3rd series of events uses a different frequency for 8.96 seconds

Or 8.96 x 3 = total of 26.8 seconds

7 x 128 x 171uS, then 8.96 seconds other frequencies, + 7 x 128 x 171uS = .306 seconds within an average 30 second period considering the random selection of hopping sequences over time.
**3.4 Channel Separation and Bandwidth**
Test Procedure:

1) Prior to making conducted measurements of the transmitter, verify the cable losses and attenuation for conducted measurements in the frequency band of interest.

2) Connect the modified radio directly to the spectrum analyzer input using the calibrated cable and attenuator. Use a 5 MHz span 100kHz resolution and video bandwidths. Set the radio to "inquiry" and "page" mode. Show the channel spacing using the delta function of the spectrum analyzer. Plot the transmitter channels.

3) Adjust the spectrum analyzer for a 2 MHz span using 100 kHz resolution and video bandwidths. Plot the spectrum of the transmitter without the hopping mode engaged. Using the peak search mode determine the peak of the channel occupancy. Calculate 6 dB down from the peak and use the display line to show the 6-dB reference. Adjust the marker to the left side of the spectrum to the display line. Using the marker delta function move to show the 6-dB bandwidth of the transmitter spectrum and plot.

4) Adjust the spectrum analyzer for a 2 MHz span using 30 kHz resolution and video bandwidths. Plot the spectrum of the transmitter without the hopping mode engaged. Using the peak search mode determine the peak of the channel occupancy. Calculate 20-dB down from the peak and use the display line to show the 20-dB reference. Adjust the marker to the left side of the spectrum to the display line. Using the marker delta function move to show the 20-dB bandwidth of the transmitter spectrum and plot.
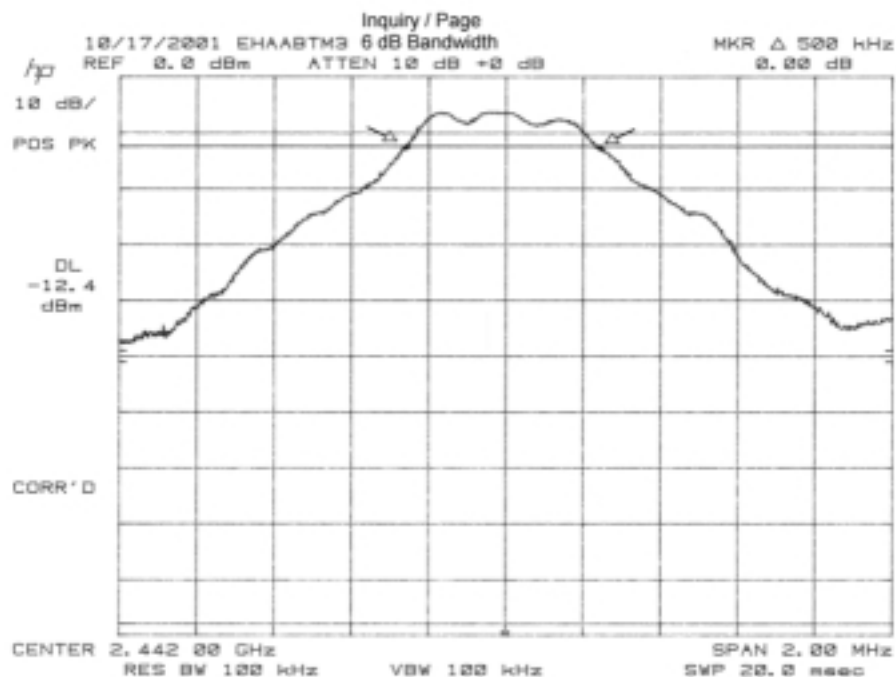

Data Plots:

Channel Spacing

20 dB Bandwidth

Intermec Technologies Corporation

DOC. NO.: 577-500-997
ABTM3 Module, FCC 15.247, Canada RSS-210, Hybrid Mode

REPORT NO: 20011018-1
DATE: October 18, 2001
Page 10 of 12
FCC ID: EHAABTM3

6 dB Bandwidth

Results:

The channel spacing equals 1 MHz. This does meet the 25 kHz minimum and is near the 878 kHz channel bandwidth.

The 20-dB bandwidth equals 878 kHz for the center channel 2442 MHz. Similar results were observed for the end channels 2402 and 2480 MHz. This meets the requirement of 20-dB bandwidth maximum of 1 MHz.

The 6-dB bandwidth equals 500 kHz for the center channel 2442 MHz. Similar results were observed for the end channels 2402 and 2480 MHz. This meets the requirement of 6-dB bandwidth maximum of 500 kHz.
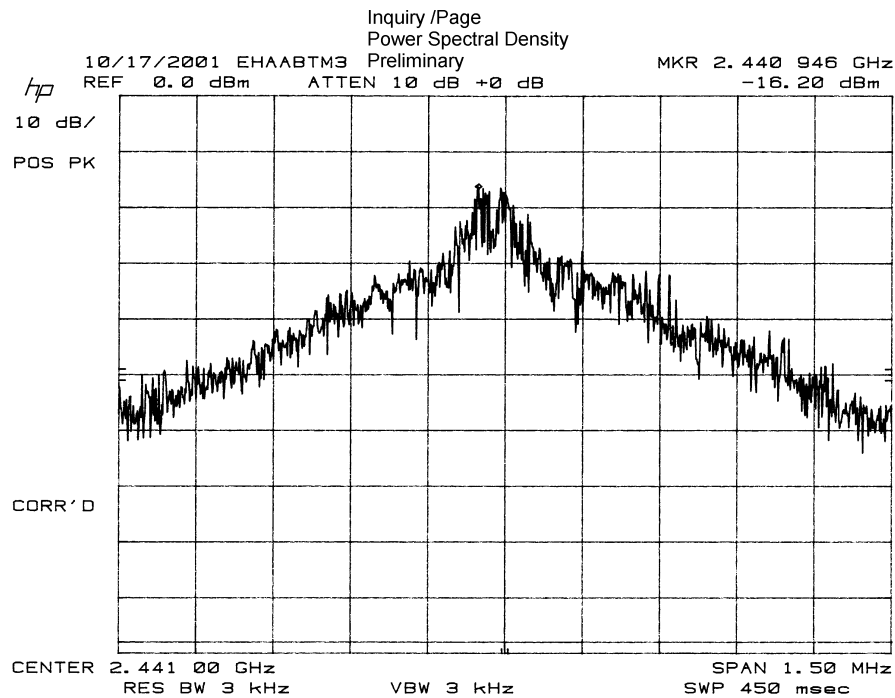

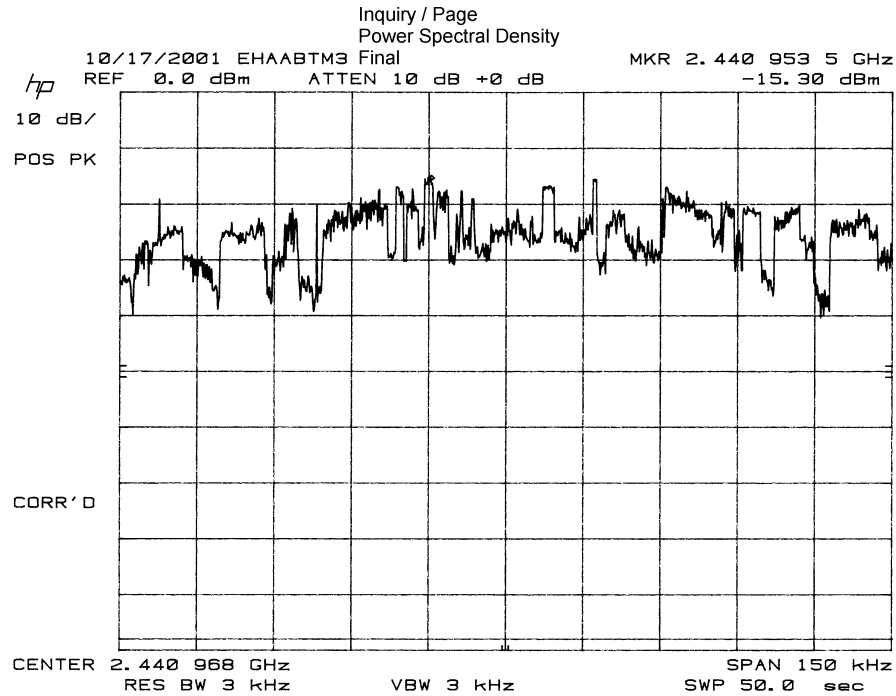

3.5 Power Spectral Density
Test Procedure:
1) Prior to making conducted measurements of the transmitter, verify the cable losses and attenuation for conducted measurements in the frequency band of interest.

2) Connect the modified radio directly to the spectrum analyzer input using the calibrated cable and attenuator. Use 1.5 MHz span, 3 kHz resolution and video bandwidths. Set the radio to "inquiry" and "page" mode. Show the peak of the channel emission using the peak search function of the spectrum analyzer. Plot the transmitter spectrum as the preliminary power spectral density.

3) Adjust the spectrum analyzer for a 150 kHz span using 3 kHz resolution and video bandwidths and set the sweep time for 50 seconds. Center the peak emission shown in the previous step on the spectrum analyzer. Plot the spectrum of the transmitter without the hopping mode engaged. Using the peak search mode determine the peak power spectral density and plot the final power spectral density.
