Appendix

- VSWR :** *Voltage standing wave ratio on a transmission line in an antenna system. The ratio of the forward to reflected voltage on the line, and not a power ratio. A VSWR of 1:1 occurs when all parts of the antenna system are matched correctly.*
- Return Loss :** *When the load is mismatched, then, not all of the available power from the generator is delivered to the load. This 'loss' is called return loss(RL).*
- Radiation pattern :** *The radiation characteristics of an antenna as a function of spatial coordinates. Normally, the pattern is measured in the far-field region and is represented graphically.*
- Polarization :** *The sense of the wave radiated by an antenna. This can be horizontal, vertical, elliptical, or circular (left or right hand circularity), depending on the design and application. The polarization of the antenna is based on the orientation of the electric or E field component. The polarization must be matched between two antennas to receive the maximum field intensity. Dependent on the antenna type, it is possible to radiate linear, elliptical and circular polarizations.*
- Gain value :** *The increase in effective radiated power in the desired direction of the major lobe.*
- Peak gain :** *The highest gain value in 360 degrees, which means the antenna efficiency at this angle is the best.*
- Cable loss :** *When RF signal transmitting in the coaxial cable, due to the material of the cable, the power may dissipate into to the air in the form of heat. So when we try to measure the gain of an antenna, we have to offset the cable loss. The power loss of coaxial cable($\Phi=1.13$ mm) at 2.4~2.5 GHz is 3dB per 1000 mm and 5dB per 1000 mm at 5.15~5.35 GHz. In this case, the cable length of the right antenna is about 502 mm, so the cable loss when RF signal transmitting at 2.4~2.5 GHz is about 1.51 dB; and the one at 5.15~5.35 GHz is about 2.51dB. For the same reason, the cable length of the left antenna is about 710 mm, so the cable loss when RF signal transmitting at 2.4~2.5 GHz is about 2.13dB; and the loss at 5.15~5.35 GHz is about 3.55 dB. Which means we have to offset the cable loss to the gain value that we measure from the radiation pattern and that is the true antenna gain (G_a) we want.*
