FCC ID #: J9CPDQ800

Mr. Kwock Chan,

In reference to our phone conversation, QUALCOMM is requesting a Class 2 Permissive Change for the dual mode PDQ800 Cellular Phone, FCC ID: J9CPDQ800. This Class 2 Permissive Change applies to the ERP Output Power listed on the grant for J9CPDQ800, that the 0.6 Watts for FM and the 0.4 Watts for CDMA, will now be nominal values. Enclosed is the SAR data at 0.955 Watts for FM and 0.630 Watts to support this permissive change request. If you have any questions, please contact me at (619) 658-3428

Sincerely,

Jay Moulton

## 1 INTRODUCTION

This test report describes an environmental evaluation measurement of specific absorption rate (SAR) distribution in simulated human head tissues exposed to radio frequency (RF) radiation from a wireless portable device manufactured by QUALCOMM Inc. These measurements were performed for compliance with the rules and regulations of the U.S. Federal Communications Commission (FCC). The testing was performed between the 11<sup>th</sup> of May 1999 and the 14<sup>th</sup> of May 1999 in the QUALCOMM SAR Test Facility. The wireless device is described as follows;

*EUT Type: CDMA/Analog Phone/Personal Digital Assistant*  
*Trade Name: QUALCOMM Inc.*  
*Model: PDQ-800*  
*Tx Frequency : 824.04 – 848.97 MHz*  
*Max. Output Power: 29.8 dBm ERP Analog and 27.3 dBm ERP CDMA*  
*Modulation: CDMA and FMAMPS*  
*Antenna: Retracting whip w/ helix*  
*Trade Name / Model: QUALCOMM PDQ-800*  
*FCC Classification: Non-Broadcast Transmitter Held to Ear*  
*Application Type: Certification*  
*Serial Number : 2399*  
*Place of Test: QUALCOMM Inc., San Diego, CA, USA*  
*Date of Test: May, 1999*  
*FCC Rule Part: 2.1093; ET Docket 96.326; part 25*

## 2 SAR TEST FACILITY

SAR tests were performed in the Qualcomm SAR Test Facility located at the following address:

Qualcomm Incorporated  
 Building AA.  
 10290 Campus Point Drive.  
 San Diego CA 92121

Company QUALCOMM Inc.	Document No. <b>80-B6165-1</b>	
<b>PDQ-800 SAR REPORT</b>	Issue No: 1	Date <b>May 1999</b>
Equipment PDQ-800	Page Number <b>4</b>	

### 3 APPLICABLE REGULATIONS

The PDQ-800 is designed to comply with the specific absorption rate SAR limits for distances within 20 cm of the transmitting elements of the MES, and with general public uncontrolled environment Maximum Permissible Exposure (MPE) limits at distances greater than 20 cm from the transmitting elements of the device, as required by Sections 1.1307 through 1.1310, 2.1091 and 2.1093 of the 47 C.F.R. (1997). These FCC RF safety limits, which are based on a hybrid combination of the SAR and MPE requirements from ANSI/IEEE C95.1-1992 and the National Council on Radiation Protection and Measurements (NCRP) report no. 86, are also consistent with the RF safety limits defined in the IRPA Guidelines on Protection Against Non-Ionizing Radiation which are reportedly in the process of being adopted in Europe, as codified in European Pre-Standard ENV 59166-2 approved by CENELEC (1994). This test report pertains specifically to the following limit from the Code of Federal Regulations 47 "Limits for General Population/Uncontrolled exposure: 0.08 W/kg as averaged over the whole-body and spatial peak SAR not exceeding 1.6 W/kg as averaged over any 1 gram of tissue (defined as a tissue volume in the shape of a cube). Exceptions are the hands, wrists, feet and ankles where the spatial peak SAR shall not exceed 4 W/kg, as averaged over any 10 grams of tissue (defined as a tissue volume in the shape of a cube)."

### 4 SAR TEST RESULTS SUMMARY

This device has been tested for localised specific absorption rate (SAR) for uncontrolled environment/general population exposure limits specified in ANSI/IEEE Std. C95.1 ~ 1992 and has been tested in accordance with the measurement procedures specified in ANSI/IEEE Std. C95.3 ~ 1992 . Normal antenna operating positions were incorporated, with the device transmitting at frequencies consistent with normal usage of the device. The device has been shown to be capable of compliance for localised specific absorption rate (SAR) for uncontrolled environment/general population exposure limits specified in ANSI/IEEE std. C95.1-1992.

Company QUALCOMM Inc.	Document No. <b>80-B6165-1</b>

Equipment PDQ-800	Page Number <b>5</b>	

## 5 TECHNICAL DESCRIPTION

The test sample consisted of a QUALCOMM PDQ-800. This model will operate in CDMA and FMAMPS analog cellular mode. The CDMA mode is designed to transmit in the 824.04 – 848.97 MHz band at a maximum transmitter output power of 23.1 dBm and a peak antenna gain of 2.2 dBd, or a maximum ERP of 25.3 dB. However, manufacturing tolerances could raise this as much as 2.0 dB so the test was performed with the power level set to **27.3** dBm ERP. The cellular FM AMPS mode is designed to transmit in the 824.04 – 848.97 MHz band at a maximum output power of 25.6 dBm with a peak antenna gain of 2.2 dBd, or a maximum ERP of 27.8 dBm. Manufacturing tolerances could possibly raise this as much as 2.0 dB so this mode was tested with the power level set to **29.8** dBm ERP.

The PDQ-800 is a dual mode phone (photos near end of report). The antenna is a standard retracting whip antenna, with a helix antenna that is at the base of the whip which gets activated when the whip is retracted. Since either position is possible during use, both retracted and extended antenna positions were tested. Four units were tested, and the unit with the highest SAR was identified, and this unit was tested at three frequencies, high, low, and mid-band, on both the left head and the right head phantom.

### 5.1 DESCRIPTION OF QUALCOMM SAR TEST FACILITY

All tests were performed under the following environmental conditions:

Temperature Range:	15 - 35 Degrees C	(Actual 20 C)
Humidity Range:	25 - 75 %	(Actual 38 %)
Pressure:	860 - 1060 mbar	(Actual 1015 mB)

All Qualcomm dosimetry equipment is operated within a shielded screen room manufactured by Lindgren RF Enclosures to provide isolation from external EM fields. The E-field probes of the DASY 3 system are capable of detecting signals as low as 5µW/g in the liquid dielectric, and so external fields are minimised by the screen room, leaving the phone as the dominate radiation source. The floor of the screen room is reflective, so four two-foot square ferrite panels are placed beneath the phantom area

Company QUALCOMM Inc.	Document No. <b>80-B6165-1</b>	
<b>PDQ-800 SAR REPORT</b>	Issue No: 1	Date <b>May 1999</b>
Equipment PDQ-800	Page Number <b>6</b>	

of the DASY system to minimise reflected energy that would otherwise re-enter the phantom and combine constructively or destructively with the desired fields. These ferrite panels provide roughly 12 to 13 dB of attenuation at the frequency of 900 MHz. Space beneath the DASY system limits the absorber type to ferrite tiles, although this attenuation combined with scattering of the energy is sufficient to bring the system validation within the acceptable tolerance.

**DOSIMETRY SYSTEM** The dosimetry equipment consists of a complete DASY3 V1.0 dosimetry system manufactured and calibrated by Schmid & Partner Engineering AG of Zurich, Switzerland, it is currently a state of the art system and from our research, it appears to be the best available at this time. The DASY3 system consists of a six axis robot, a robot controller, a teach pendant, automation software on a Pentium 200 MHz computer, data acquisition system, isotropic e-field probe, and validation kit.

**E-FIELD PROBE** This test was performed using an E-field probe with conversion factors determined by Schmid & Partner (S & P). The probe is the most important part of the system, so will be discussed in section 5.2.

**PHANTOM** The phantom was the so called "generic phantom" supplied by S & P, and consists of a left and right side head for simulating phone usage on both sides of the head. The phantom is constructed of fibreglass with 2 +/- 0.1 mm shell thickness. The shape of the shell is based on data from an anatomical study of a group of 33 men and 19 women to determine the maximum exposure in approximately 90% of all users. The DASY system uses a homogeneous tissue phantom based on studies concerning energy absorption of the human head, and the different absorption rates between adults and children. These studies indicated that a homogeneous phantom should overestimate SAR by no more than 15% for 1 g averages and should not underestimate SAR. In similar studies it was found that a typical ear thickness is approximately 4 mm, so a 2 mm rubber ring is attached to the phantom at the ear area, so that combined with the 2mm fibre glass shell the total thickness is close to 4 mm.

**LIQUID DIELECTRIC** The tissue simulating liquid which fills the phantom is supplied by Schmid & Partner. Before the test the permitivity and conductivity were measured with an automated Hewlett Packard 85070B dielectric probe in conjunction with an HP 8752C network analyser to monitor permitivity change due to evaporation. The electromagnetic parameters of the liquid were maintained as shown in table 1. The

Company <b>QUALCOMM Inc.</b>	Document No. <b>80-B6165-1</b>

target values were obtained from the FCC web page for Tissue Dielectric Properties with internet address [www.fcc.gov/fcc-bin/dielec.sh](http://www.fcc.gov/fcc-bin/dielec.sh).

<b>FREQUENCY</b>	<b>PERMITIVITY</b>	<b>CONDUCTIVITY</b>	<b>DENSITY</b>
900 MHz	42.7 +/- 5%	.88 +/- 10% mho/m	1 g/cm <sup>3</sup>

Table 1

The E-field probe is calibrated by the manufacturer in brain simulating tissue at frequencies of 900 MHz, accurate to +/- 8%. Linearity is said by the manufacturer to be +/- .2 dB from 30 MHz to 3 GHz. Dynamic range is said by the manufacturer to be 5  $\mu$ W/gm to > 100 mW/g. The probe contains 3 small dipoles positioned symmetrically on a triangular core to provide for isotropic detection of the field. Each dipole contains a diode at the feed point that converts the RF signal to DC, which is conducted down a high impedance line to the data acquisition system.

The data acquisition system amplifies the signals, and converts them to digital values so that they may be sent to the computer. The inputs to the signal amplifiers are auto zeroed after every measurement to prevent charge build up on the lines, which could lead to errors.

## 5.2 SAR SYSTEM THEORY

The human body absorbs energy from a radiating cell phone by ionic motion and oscillation of polar molecules. The human head is in the near field of the device where polarisation and field intensity are very complex. Also the human head can cause large reflections and scattering, so it is more practical to measure the field absorbed inside the head, than to measure incident power before it enters the head. Inside the lossy brain tissue, the power per unit volume is given by (next page):

Company QUALCOMM Inc.	Document No. <b>80-B6165-1</b>	
<b>PDQ-800 SAR REPORT</b>	Issue No: 1	Date May 1999
Equipment PDQ-800	Page Number <b>8</b>	

$$P_v = 1/2 \mathbf{J} \cdot \mathbf{E}^* = 1/2 \sigma |\mathbf{E}|^2 \quad \text{W/m}^3$$

where  $\mathbf{J}$  is current density

$\sigma$  is conductivity of human tissue due to conductive and lossy displacement currents.

$\mathbf{E}$  is the electric field

But since SAR is the absorption of RF power per unit mass

$$P_g = 1/2 \sigma / \rho |\mathbf{E}|^2 \quad \text{W/kg}$$

where  $\rho$  is density of the tissue in kilograms per cubic meter.

In this equation,  $\sigma$  is a function of frequency, and so it must be measured at the frequency of the test. It is measured in terms of the real and imaginary components of the complex permittivity;

$$\epsilon = \epsilon_0 (\epsilon' - j\epsilon'')$$

$$\sigma = 2\pi f \times (8.854 \times 10^{-12}) \times \epsilon''$$

$$\text{Loss Tangent} \equiv \tan \delta = \epsilon'' / \epsilon'$$

In order to measure the E field strength without distorting the field, the E field probe (shown here) is made as described by Schmid, Egger, and Kuster in [3].

E-field Probe

<b>PDQ-800 SAR REPORT</b>	Issue No: 1	Date <b>May 1999</b>
Equipment PDQ-800	Page Number <b>9</b>	

A major concern is that secondary coupling of the EUT radiated fields to the feed lines of the probe are minimised. This is done by making the feed lines of high impedance "twin-line" transmission line, printed very close together. In the probe tip there are three orthogonal dipoles, electrically small to minimise field distortion from coupling. The electrically small dipoles have source impedance's of 5 to 8 MΩ due to their small size, the high resistive feed lines, and the distributed filters on the lines. This high impedance makes them less sensitive so a sophisticated Data Acquisition Electronics (DAE) box is needed to amplify, multiplex, and digitize the signals. The DAE is installed on top of the robot arm. It also detects the proximity of the phantom surface with a fiber-optic cable. It provides for multiplexing between the three dipoles, and between 1X gain and 100X amplification, and it provides some filtering that will remove unwanted signals picked up by the probe. The DAE also provides a fast digital link to the robot for stopping in the event of a touch detection. It samples the probe output for 2600 complete E field measurements per dipole, per second. These samples are used to determine the amplification needed, 1X or 100X, and the magnitude determines what diode compression correction factor should be used. These factors as well as sensitivity factors of the specific probe, which are stored in the program, are used to determine the actual field strength for the test point.

The substrate on which the dipoles are printed, has been shaped to align each dipole with the E-field *after* the field lines are distorted by the permittivity of the substrate. In other words, since the substrate and the liquid dielectric have differing permittivities, the E-field will diffract as it passes through the interface, and so the dipoles have been positioned to align with the fields *after* this distortion is accounted for.

The dipole elements in the probe are offset from the tip of the probe approximately 2.7 mm so unfortunately the field strength cannot be measured at the surface of the phantom, where it is likely to be maximum. The magnitude of the field at the surface must therefore be calculated with interpolation by using the data points stepped away from the surface and curve fitting, this is done automatically by the software .

Equipment PDQ-800	Page Number <b>10</b>	

## 6 TEST SAMPLE OPERATION

The wireless device was made to transmit maximum power using a Tektronix CMD-80 with the "voice MAC" set to 0 in the power control window. This insures maximum power is transmitted during the test, a similar setting is used for the CDMA mode with the label "max output power". The device has no wires or cables connected to it during the test, and maximum power is verified with an RF power meter.

## 7 CALIBRATION DATES OF TEST EQUIPMENT

All measurements were made with instruments whose operation and accuracy has been verified by a Calibration Laboratory with traceability to National standards. The calibration dates for each measurement instrument is shown in the following table.

<u>EQUIPMENT MANUFACTURER &amp; TYPE</u>	<u>SERIAL NO.</u>	<u>LAST CAL.</u>	<u>NEXT CAL.</u>

## 8 SAR TEST SYSTEM VALIDATION

Before the test, the system was validated using a symmetric dipole designed to be impedance matched when pressed against a machined dielectric spacer, touching the phantom filled with the brain simulating fluid. The separation distance between the validation dipole and the flat phantom is maintained at a fixed distance from dipole center to solution surface with a machined plastic spacer, manufactured for the validation kit. The measured permittivity and conductivity was entered into the DASY settings window (there are slight variations in the permittivity from day to day due to evaporation, although water is added to minimise the variation) A signal generator was used to generate a very stable .01 Watt continuous wave signal, which was checked with an HP RF power meter (calibrated to 900 MHz) several times over a 30 minute period (to eliminate drift by reaching stable temperature), then input to the validation dipole. Then the DASY3 system was put through an automated validation cycle to determine if the correct SAR is measured. The correct SAR was determined by Schmid & Partner to be .0944 mW/gm for the D900V2 dipole. These values measured indicate that the system is measuring correctly at these frequencies.

If the validation result were to give a value high or low by more than 4%, the liquid is re-measured to check for evaporation, and other parameters are checked until this validation produces the correct SAR value. Parameters frequently checked if the validation gives erroneous SAR include diode compression factors, probe conversion factors, frequency settings for the probe, frequency, permittivity, and conductivity settings for the liquid, placement of ferrite panels beneath phantom, drift in the signal generator, power meter calibration settings, stirring of the liquid dielectric, or the teaching of the robot the exact location of the phantom. This is the main validation test for the system configuration.

Over a period of several days, the robot loses the exact position of the phantom, this information is stored in memory and must be "re-taught" to the system. Before each day of measuring begins, the robot is sent to 3 test points on the phantom to determine if the exact position information has been lost. If so, the robot is sent to these three points manually and the computer is told to record the information from position sensors in the robot joints. This insures that the system can place the probe as close as possible to the phantom surface.

## SAR SYSTEM SPECIFICATIONS

### Data Acquisition

Processor: Pentium 200 MHz  
 Operating Sys: Windows  
 Software: DASY3 V1.0b Dec 97 edition, Schmid & Partners Eng. AG, Switzerland  
 Amplifier Gain: 10X or 100X depending on signal level  
 Surface Detection: Optical and Mechanical  
 Sample Rate: 7800 data sets per second  
 Isolation: Fiber Optics to computer, 100K $\Omega$ / $\square$  to probe tip

### E-Field Probe

Offset tip to sensor center: 2.7 mm  
 Offset surface to probe tip: 1.8 +/- 0.2  
 Frequency: 30 MHz to 3.0 GHz  
 Dynamic Range: 5 $\mu$ W/g to 100 mW/g  
 Isotropy: +/- .15 dB (in brain liquid)

### Phantom

Dielectric: Homogeneous sugar/salt/cellulose liquid  
 Shell: 2 mm +/- 0.2 mm polyester fiber glass  
 Ear: 2mm rubber ring

### Liquid Dielectric

Permittivity: 42.7 @ 900 MHz  
 Conductivity: .88 S/m @ 900 MHz

<b>PDQ-800 SAR REPORT</b>	Issue No: 1	Date <b>May 1999</b>
Equipment PDQ-800	Page Number <b>13</b>	

## 9 SAR MEASUREMENT PROCEDURE

**DEVICE POSITIONING** The phone was tested in the test position which was described by Supplement C of OET Bulletin 65 from the Office of Engineering & Technology, of the FCC. This procedure places the surface of the phone in contact with the phantom at the ear with the speaker aligned with the ear canal. The phone is moved toward the cheek until the keypad area makes contact with the cheek of the phantom, insuring minimum separation and 3 points of contact, 2 at the ear and one in the cheek area. This procedure insures the highest possible SAR values are measured.

**CREST FACTOR** To compensate for probe diode compression with strong signals, the DASY3 system software utilizes the crest factor (the ratio of peak to RMS signal level) of the measured waveform to scale a second order correction term in the output voltage from the probes. The correction factor is applied using the following built-in equation to each (x, y, z) probe channel:

Channel signal voltage = input signal + [(input signal)<sup>2</sup> \* crest factor / diode compression point ]

Both the crest factor and the diode compression point are DASY3 system input parameters; the latter probe specific, the former waveform specific. For small measured signals the crest factor selected is immaterial, but the system requires that one be specified. For a TDMA waveform the crest factor is simply the inverse of the duty cycle (a factor of 8 for GSM signals). For CDMA waveforms the crest factor must be measured. This Crest factor was measured using a Gigatronics 8542 C Power meter with a power sensor model 80601 A.

**CUBE EVALUATION** The explanation of the fine scan, or cube evaluation is given in the manual for the DASY system by Schmid & Partners, and is repeated here.

The spatial peak SAR value for 1 and 10 g is evaluated after the cube measurements have been done. The algorithm that finds the maximal averaged volume is divided into three different stages.

Company <b>QUALCOMM Inc.</b>	Document No. <b>80-B6165-1</b>	
<b>PDQ-800 SAR REPORT</b>	Issue No: <b>1</b>	Date <b>May 1999</b>
Equipment <b>PDQ-800</b>	Page Number <b>14</b>	

(1)The data between the dipole center of the probe and the surface of the phantom is extrapolated. This data cannot be measured because the dipoles are 2.7 mm away from the actual tip of the E-field dosimetry probe, and the distance between the surface and the lowest measuring point is approximately 1 mm. So they can never be placed in the field at the surface of the phantom. The extrapolation is based on a least square algorithm [W. Gander, Computermathematik, p. 168 – 180]. Through the points in all z-axis polynomials of order four are calculated. This polynomial is then used to evaluate the points between the surface and the probe tip. The points calculated from the surface, have a distance of 1 mm from one another.

(2)The maximal interpolated value is searched with a 3d-spline. The 3d-spline is composed of three one-dimensional splines with the “Not a knot” condition [W.Gander, Computermathematik, p.141 – 150] (x, y, and z direction) [Numerical Recipes in C, Second Edition, p.123ff]. Around this maximum the SAR values averaged over the spatial volumes (1g or 10g) are computed using the 3d spline interpolation algorithm. If the volume cannot be evaluated (i.e., if part of the grid was cut off by the boundary of the measurement area) the evaluation will be started on the corners of the bottom plane of the cube.

(3)All neighboring volumes are evaluated until no neighboring volume with a higher average value is found.

For the volume averaging the size of the cube is first calculated. The volume is then integrated with the trapezoidal algorithm. 1000 points (10 x 10 x 10) are interpolated to calculate the average.

Typically the maximum SAR values occur on the outer boundary of the liquid nearest the radiation source, at the fluid-phantom shell interface. The extrapolation of this maximum will indicate that the maximum is outside of the measurable area. When this occurs the DASY system writes the comment “maximum outside” on the SAR plots. This is not an indication of a bad measurement, but indicates that the maximum was extrapolated since it was physically impossible to measure.

## 10 SAR MEASUREMENT UNCERTAINTY

The possible errors included in this measurement arise from device positioning uncertainty, device manufacturing uncertainty, liquid dielectric permittivity uncertainty, liquid dielectric conductivity uncertainty, uncertainty due to disturbance of the fields by the probe.

These will be discussed as they are of much importance to the final dosimetric assessment. Every attempt is made to reduce uncertainty, as well as to test for worst case SAR. These uncertainties are likely to be pessimistic, but they should be considered when comparing data taken from one lab to another. Thomas Schmid of Schmid and Partners has performed a study of SAR repeatability due to many different uncertainties, this is likely the most complete study of the topic so it is referred to here.

**Device positioning;** this uncertainty is due to different operators positioning the device on the phantom differently, it depends on the operators, the device design, the phantom, and the device holder. Repeatability for some devices in Schmid's study was as poor as +/- 30% for the "touch" position. For the "intended use" position the repeatability was approximately +/- 5%, depending on the device tested, overall a figure of +/- 6% was taken as typical device positioning uncertainty. One operator is used at the QUALCOMM lab, trained to place the phone as close as possible to phantom, and the test is performed after the position of maximum SAR is determined. This minimises device positioning error. Typically the phone is clamped in the holder in the horizontal position, and a short wooden dowel is placed in a small hole where the center of the ear speaker resides, this wooden dowel allows the operator to line up the speaker with the ear canal. Once aligned, the tooth pick is removed, and the phone is raised up until it touches the phantom on the ear. Then the cradle is rocked so the phone rocks toward the chin of the phantom, touching as closely as possible without depressing the keypad. This puts the phone as close as possible to the phantom, allowing maximum SAR to be measured, for most positions. In the event that this may not produce maximum SAR, the phone is placed in several other positions and a coarse scan is run for each position. The DASY system has a command called "move to max" which allows the probe to be sent to the point of max field intensity found with the coarse scan. This gives a visual indication of where the maximum surface currents may be, and allows the operator to position this point of the phone as close as possible to the phantom.

Company QUALCOMM Inc.	Document No. <b>80-B6165-1</b>	
<b>PDQ-800 SAR REPORT</b>	Issue No: 1	Date <b>May 1999</b>
Equipment PDQ-800	Page Number <b>16</b>	

**Liquid dielectric permittivity and conductivity;** The average permittivity of a typical human head was determined by Dr. Gabriel and has been listed by the FCC (OET bulletin 65 supplement C) as 46.1 at 835 MHz. The liquid purchased from Schmid & Partner measures approximately 42.7 at 900 MHz. The lower permittivity generally gives a slightly higher SAR value, so these values were used for the test. Since SAR is defined as the time rate of absorption per unit of weight, only the macroscopic simulation of the tissue's permittivity, permeability, and conductivity are required. These electrical properties are obtained with a liquid which uses sugar to raise the permittivity, salt to raise the conductivity, and cellulose to hold the two in suspension. The QUALCOMM lab purchases the dielectric from Schmid and Partners so that maximum accuracy of permittivity and conductivity is insured, by eliminating any possibility of liquid preparation errors, i.e. lumps in cellulose, excess viscosity causing excess bubbles, etc After receiving the liquid it is measured with an HP 85070A dielectric probe kit. The achievable accuracy of this device is +/- 5% for the permittivity and +/- 10% for the conductivity. The permittivity and conductivity match with those claimed by Schmid & Partners. The liquid is also measured at the beginning of each SAR measurement day, to check for evaporation.

**FIELD DISTURBANCES** Errors due to disturbance of the fields by the probe; because the polarisation of the fields are unknown, the near field probe must measure all polarisation's without disturbing them by being present. Three orthogonal dipoles are located at the tip of a special dielectric support, with diodes at the feed points sensitive to fields as small as 5 microWatt/gm. To prevent secondary coupling of the fields to the feed lines, the lines are high resistance printed lines with distributed filters integrated in the lines, after the diode. Much research has been put into these probe designs, so their uncertainty is considered minimized. There are other uncertainties, such as laboratory setup uncertainty, the reader should refer to attachment 10 of the March 1998 minutes of the IEEE standards coordinating committee, by Thomas Schmid. Mr. Schmid's preliminary uncertainty figure is -12% to +52% for the SAR measurement. As stated before this is possible, but believed to be pessimistic because many of the sources of uncertainty have been reduced or eliminated, at considerable expense. All practical precautionary measures are taken to reduce these errors in the QUALCOMM Inc. SAR lab.

## 11 TEST DATA SUMMARY

The device which was tested is the final production model without the analogue and digital cellular software loaded. No more design changes are to be made which will effect SAR. The device represents the frozen design of the PDQ-800.

The SAR values measured for the PDQ-800 are given below as well as a listing of the measurment conditions and the ANSI/IEEE C95.1 1992 limits.

Ambient TEMPERATURE (°C) 20 C  
Relative HUMIDITY 38%  
Atmospheric PRESSURE 1015 mB

Mixture Type: Water/Sugar/cellulose/Salt  
Dielectric Constant: 42.7  
Conductivity: .88 +/- 10% mho/m  
Closest Distance between E-Probe & Phone Antenna 1.85 Inch (intended use position)
