Statement of Compliance: BlackBerry RTS declares that the product was tested in accordance with the appropriate measurement standards, guidelines and recommended practices.

This Blackberry® Smartphone is a wireless portable device and has been shown to be in compliance with FCC 20.19 (2014-10-1), Hearing Aid-Compatible Mobile Handset and FCC Guidance KDB 285076 D01, V04, October 2013 and has been tested as per ANSI C63.19-2011.

1.0 Introduction

This test report documents the measurements of the near electric/ RF Audio Interference Level generated by a wireless communication device in the region where a hearing aid would be used. The measurement procedures of ANSI C63.19-2011 were followed along with the guidance provided by the FCC.

The electric field from a wireless device is measured using a SPEAG DASY5 automated system with HAC extension and free-space probes (ER3DVx) in a 5cm x 5cm area, 15mm above the wireless device's acoustic output and the centre point of the probe element. The area is divided into 9 sub-grids and the maximum values of the electrical field scans are evaluated automatically according to the rules defined in the standard and the device is assigned a certain category. Should the wireless device's maximum T-Coil output occur in a location other than the centre of acoustic output, then the RF field scans are repeated with the measurement area centered on the maximum T-Coil output location.

The DASY5 HAC Extension consists of the following parts: the Test Arch phantom, three validation dipoles, dipole and DUT holders, electric field probes and DASY5 software. The field probes and measurement electronics are described in Annex B.1.

The specially designed Test Arch allows high precision positioning of both the device and any of the validation dipoles. The broadband dipoles are calibrated at a single frequency and are used for system performance checks.

In order to correlate the usability of a hearing aid with a wireless device (WD), the WD's radio frequency (RF) and audio band emissions are measured. ANSI C63.19 requires:

● Radio frequency (RF) measurements of the near-field electric and magnetic fields emitted by a WD in the vicinity of the audio output to categorize these emissions for correlation with the RF immunity of the microphone mode of operation of a hearing aid.
● Audio frequency magnetic field measurements of a WD emitted in the vicinity of the audio output to categorize these emissions for correlation with the T-Coil mode of operation of a hearing aid.

Hence, the following measurements are made for the WDs:
1. RF E-Field emissions.
2. T-Coil mode, magnetic signal strength in the audio band.
3. T-Coil mode, magnetic signal and noise articulation index.
4. T-Coil mode, magnetic signal frequency response through the audio band.
5. RF T-Coil environment: The worst case M rating from E-field 5x5 cm scan centered at the axial T-coil highest peak location.

5.0 Measurement procedures and measurement system

5.1 System/Dipole Validation

The test setup should be validated when first configured and verified periodically thereafter to ensure proper function.

The HAC validation dipole antenna serves as a known source for an electrical and magnetic RF output.

1. The dipole antenna was placed in the position normally occupied by the WD.
2. The dipole was energized with a 20 dBm un-modulated continuous-wave signal.
3. The center point of the probe element(s) are 15 mm from the closest surface of the dipole elements.
4. The length of the dipole was scanned with E-field probe and the maximum value was recorded.
5. The readings were compared with the values provided by the probe manufacturer and were found to agree within tolerance of +/- 10%. Please refer to Annex A.2 for Dipole Validation Plots.

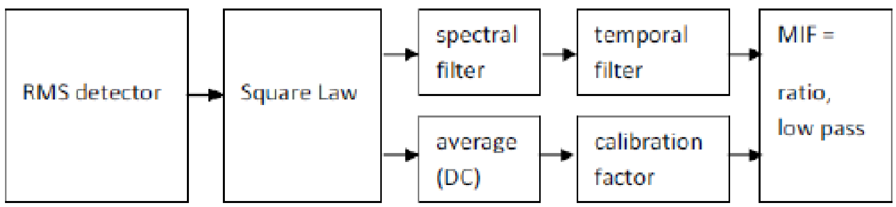
5.2 Modulation interference factor (MIF)

For a modulated signal, the difference, in dB, determined by subtracting the signal's steady-state level, in dB, from its radio-frequency (RF) audio interference level, in dB.

MIF is the weighted envelope of a square law detector, relative to its carrier. The weighting consists of a spectral part (extracting the audible parts with a weighting similar to an A-weighting curve) followed by a quasi peak detector. Because it is used to scale the power-averaged field, the weighted quantity is relative to the carrier signal. The unmodulated carrier would not pass the spectral _filter; therefore the reference signal is defined for the carrier when the amplitude is modulated with 1 kHz and 80% AM depth.



5.2-1 RF interference level measurement

For any specific fixed and repeatable modulated signal, a modulation interference factor (MIF, expressed in dB) may be developed that relates its interference potential to its steady-state rms signal level or average power level. This factor is a function only of the audio-frequency amplitude modulation characteristics of the signal and is the same for field-strength and conducted power measurements.

A Wireless Device's interference potential is a function both of the WD's average near-field field strength and of the signal's audio-frequency amplitude modulation characteristics. The portion of the interference potential attributable to the modulation characteristic can be evaluated independently of any particular WD. This evaluation of this interference potential relative to a signal's average field strength is described , and it is called its modulation interference factor (MIF).

5.3 Evaluation of Interference Potential

A WD's interference potential is a function both of the WD's average near-field field strength and of the signal's audio-frequency amplitude modulation characteristics. The portion of the interference potential attributable to the modulation characteristic can be evaluated independently of any particular WD. This evaluation of this interference potential relative to a signal's average field strength and its modulation interference factor (MIF). The MIF may be determined through analysis and simulation, allowing evaluation of an RF technology's RF interference potential in advance of actual product development.

5.4 AIA Audio Interference Analyzer

The AIA is an USB powered electronic sensor to evaluate signals in the frequency range 698 MHz - 6 GHz. It contains RMS detector and audio frequency circuits for sampling of the RF envelope. In addition to the measurement circuits, the AIA contains calibration circuits which are activated immediately before the measurement for system verification. After the calibration interval is completed, the applied signal is evaluated. All filtering and evaluation is applied to the digitized raw signal with digital IIR _filters in the DASY52 software.

The RF input signal can be directly connected to the RF. The resulting coupling factor (CF) can be compensated for in the software settings to obtain the averaged power reading for evaluation of the RF Audio Interference Potential (RFAIP).

Figure 5.4-1: Audio Interference Analyzer

5.5 MIF Measurement using AIA

The DASY52 MIF measurement job and Audio Interference Analyzer (AIA) manufactured by SPEAG, part number: **SE UMS 170 CA, serial number:1016** were used to evaluate the MIF, PMF, RF level at the internal detector and RF Audio Interference Potential (RFAIP) of RF signals.

MIF measurement is done as follows:

- AIA is connected to the DASY5 via USB.
- RF signal is connected conducted with enough attenuation to be evaluated to an AIA via cable.
- Prepare and run a MIF measurement job with correct measurement port and timing.

Table 5.5-1: MIF measurement data for GSM and UMTS/WCDMA

Please refer to Annex A.2 for MIF measurement data.

Justification for lower measured MIF than the target values:

Delta between measured and target MIF values for GSM signal is -0.06 dB which is insignificant and expected within measurement uncertainty.

Delta between measured and target MIF values for WCDMA signal is -5.91 dB due to different equipment, software and system being used. Worst case HAC RF rating is M4 with large margin of > 17 dB from the limit.

5.6 Near-Field RF Emission

The following procedure was used to measure RF near E-field emission:

1. Proper operation of the field probe, probe measurement system, other instrumentation, and the positioning system was confirmed.
2. The WD was oriented in its intended test position with the reference plane in the horizontal plane and was secured in the device holder to maintain position accuracy.
3. A CMU 200 Base Station Simulator was used to place a normal voice call to the WD on the desired channel and to transmit at maximum power.
4. The DASY5 system measures power drift as part of each scan. If the power during a scan drifted by more than 0.20 dB, the scan was repeated. Power drift measurements for the worst-case scans are included in Annex A.3. A fully charged battery was used for each test.
5. The 5cm x 5cm measurement grid was centered on the center of the acoustic output or the T-Coil output, as appropriate. The field probe was located at the initial position at the center of the measurement grid.
6. A surface verification was performed before each setup change to ensure repeatable spacing and proper maintenance of the measurement plane.
7. The electric field probe was used to measure the highest field strength in the 5cm x 5cm reference plane. The center point of the probe measurement element(s) shall be held 15 mm from the WD reference plane.
8. The entire 5cm x 5cm region was scanned with a 5mm step size. The reading was recorded at each measurement location. Justification of the step size and interpolation used is provided at the end of Annex A.2.
9. Around the center sub-grid, five contiguous sub-grids were identified with the lowest maximum field strength readings. Please note that a maximum of five sub-grids can be excluded.
10. The highest field reading was identified within the non-excluded sub-grids
11. The highest field reading was converted from average to **RF Audio Interference Level dB (V/m)** , as appropriate. This conversion was done by the DASY5 SEMCAD processor after inputting measured MIF.
12. The highest reading was compared to the categories defined in C63.19.

- If a WD has more than one antenna position, it is necessary to test the WD only in the condition of maximum antenna efficiency, i.e. antenna extended.

- The WD's backlight shuts off automatically a short time after a call is established.

Table 6.0-2–E-Field Data Summary

Note 1: As per C63.19-2011: RF air interface technologies that have low power have been found to produce sufficiently low RF interference potential, so that it is possible to exempt them from the product testing. Evaluation of the MIF for the worst-case operating mode. An RF air interface technology of a device is exempt from testing when its average antenna input power plus its MIF is ≤17 dBm for any of its operating modes. An RF air interface technology that is exempted from testing by either method shall be rated as M4.

6.1 Conclusion

The BlackBerry® Smartphone Model: **RHK211LW (STV100-1)** is categorized to be **M3T4** based on HAC RF Emission and ABM HAC T-Coil performance in accordance with ANSI C63.19-2011: American National Standard for Methods of Measurement of Compatibility between Wireless Communication Devices and Hearing Aids.

Therefore, the device is found to be in compliance with the requirements of FCC 47 CFR 20.19 (2014-10-01) Hearing Aid-Compatible Mobile Handsets.

7.1 Site-Specific Uncertainty

RF Reflections

Section 4.2 of ANSI C63.19 requires that any RF reflecting objects are a minimum distance of 2 wavelengths away from the WD under test. For this WD, the longest wavelength occurs when the WD is transmitting at 824.7MHz. The wavelength is:

$$\lambda = \frac{c}{f} = \frac{3 \cdot 10^{8}\, m/s}{824.7 MHz} = 0.364m$$

Therefore, 2 wavelengths result in a distance of 0.73m. Tests are performed in an RF shielded chamber. The distance to the nearest wall is > 1m and the distance to the robot's safety guardrail is ~1.0m, both satisfying the requirement. In addition, RF absorbing cones are placed at the base of the robot to further reduce reflections. The HAC phantom arch is made of low dielectric constant plastic and should not be a source of reflections.

Environmental Conditions

During measurements, the temperature of the test lab was kept between 21^{o}C and 25^{o}C and relative humidity was maintained between 20% and 55%.

Ambient Noise

ANSI C63.19 standard requires RF ambient noise to be at least 20dB below the measurement level. Scans of RF ambient noise fields were previously performed for verification and was determined to be < 20 dB than the measured WD RF field levels.
