## **TEST REPORT**

### **INTRODUCTION**

The Hexagram Model 09001 transceiver is a “Meter Transmitting Unit” (MTU) designed to provide remote meter reading capability for utility meters that provide a pulsed output. The transceiver is self-powered and connects to a meter pulse output with an electrical cable. An on-board battery provides power. The transmitter provides a very short, intermittent radio frequency transmission to provide a remote reading of the meter. A microprocessor provides timing, control and data processing functions. The built in antenna is inaccessible to the user and no provision is made for an external antenna. The receiver can be used for upgrading firmware, requests for meter reads or other options available in the system. Due to the availability of units, various units were used for testing. The revision and serial number of each unit tested is shown in the appropriate section. There are no differences in the RF section of the units tested. This report presents the data obtained in support of an application for certification.

### **MEASUREMENTS PERFORMED**

Power Output and Spurious Emissions	Page 3
Occupied Bandwidth	Page 9
Frequency Stability vs. Temperature	Page 11
Frequency Stability vs. Supply Voltage	Page 12
Transient Stability	Page 14

The microprocessor and receiver portions of the transceiver were also examined for radiated emissions per Part 15, and have been verified to comply with the appropriate sections of that part. The data used for verification of the microprocessor and receiver is presented in a separate report.

## **POWER OUTPUT AND SPURIOUS EMISSIONS**

Within the tuning range of 450 – 470 MHz, the transmitter portion was examined at three fundamental frequencies and their harmonics. All measurements below 1 GHz were made at a 3-meter distance on the Smith Electronics open area test site located at 8200 Snowville Road, Brecksville, OH. Data pertinent to this site is on file with the FCC (Reg.#90938) and Industry Canada(File #4541A-1). The harmonic measurements above 1 GHz were made at a distance of 1 meter over a suitable ground plane. The measurements were made using the substitution method described in TIA/EIA-603-A.

Tuned dipoles were used for measurements below 1000 MHz and a wave-guide antenna was used above 1000 MHz. A spectrum analyzer was used as a receiver.

The transmitter was placed on a remotely rotatable, non-conducting test stand. This general set up is shown in Pictorial 1. Because of the intermittent nature of the normally operating transmitter a larger, external battery pack was connected directly to the transmitter and the transmitter was forced to continually transmit for these measurements. A ferrite bead was placed on the battery leads to minimize emissions.

With the test receiver tuned to the unmodulated signal, the transmitter under test was rotated to the position of maximum signal. The receiving antenna was then varied between 1 and 4 meters in height to again maximize the signal. Measurements were made with the antennas positioned both vertically and horizontally and the maximum signals recorded.

Peak detection was used for the signals below 1000 MHz and average detection above 1000 MHz.

After the maximum received meter readings were obtained for each frequency and polarity, the transmitter under test was removed from the area and replaced by a signal generator and transmitting antenna. With the transmit antenna placed as close as possible to the position of the test unit, the signal generator was activated at a test frequency. With the signal detected, the receiving antenna was positioned for maximum reception. The signal generator output was then adjusted until the received signal was equal to the previously received signal from the unit under test. These measurements were repeated for each frequency and antenna orientation and the maximum values obtained are noted in Tables 1a – 1c.

In order to convert the signal generator output value to equivalent radiated power from a dipole, the following equation is used:

$$P_d = P_g - \text{cable loss(dB)} + \text{antenna gain(dB}_d)$$

where:

$P_d$  is the dipole equivalent power in dBm,  $P_g$  is the generator output into the substitution antenna, also in dBm, and “antenna gain” is the gain of the substitution antenna with respect to a theoretical dipole.

According to 90.210(d)(3) all emissions greater than 12.5 kHz from the center of the authorized band shall be attenuated below the unmodulated carrier by  $50 + 10\log(P)$ . The determined power outputs, the required harmonic attenuation as well as the attenuation for each harmonic are found in Tables 1a – 1c.

**OCCUPIED BANDWIDTH**

The emissions close to the center of the specified channel are limited by the emissions masks described in 90.210. For the frequency range of the 09001 transmitter, Mask D is specified. From the center frequency of the band  $\pm 5.625$  kHz, 0 dB of attenuation is required. From 5.625 kHz to 12.5 kHz from the center frequency, attenuation must be at least  $7.27(f_d - 2.88 \text{ kHz})$  dB, where  $f_d$  is the displacement frequency from the center of the band in kHz.

At more than 12.5 kHz from the band center, the attenuation must be 70 dB or  $50 + 10 \log(P)$ , whichever is less. Since the maximum P was determined to be 0.148 W,  $50 + 10 \log(0.148)$  equals 41.7 dB (50 dB is shown in Fig. 1).

Both modulated and unmodulated transmissions were stored on the spectrum analyzer display. The plot of Fig. 1 shows both signals with Mask D superimposed on the plot. The plot indicates that the modulated emission does comply with the requirement for occupied bandwidth as found in 90.210.

For purposes of this test, the modulated signal was PN9 modulated at the specified 7200 bits per second data rate.

### **FREQUENCY STABILITY VS. TEMPERATURE**

The temperature stability of the frequency generating components of the transmitter was observed. The transmitter was placed in a temperature chamber with a programming coil that allows a transmission to be requested from outside the chamber. A receiving antenna outside the chamber picked up the transmitted signal, which was fed to the real-time spectrum analyzer.

With the transmitter programmed to transmit at 460 MHz, the chamber temperature was set to 20° C. After reaching the set temperature, the transmitter was allowed to stabilize. The transmitted signal was captured by the real-time spectrum analyzer and the frequency was determined. The temperature in the chamber was then increased to 30° C. At each temperature, at least 30 minutes were allowed for stabilization of the transmitter, a transmission was made and the frequency determined. The temperature was increase in 10° C intervals to 80° C and then to 85° C. The temperature was then returned to 20° C. stabilized and the decreased to -30° C in 10° intervals. The temperature was stabilized at each 10° interval before a reading was made. The frequency at each temperature was recorded, compared to the 460 MHz tuned frequency, and is recorded in Table 2. It can be seen from the table that all readings are within the deviation limit of  $\pm 2.5$  ppm or 1150 Hz at 460 MHz.

**TABLE 2  
FREQUENCY STABILITY  
VS. TEMPERATURE  
460 MHz**

Temperature ° C	Measured Frequency MHz	Dev. Hz	Dev. ppm
+20	460.000391	391	+0.85
+30	460.000313	313	+0.68
+40	460.000313	313	+0.68
+50	460.000313	313	+0.68
+60	460.000391	391	+0.85
+70	460.000391	391	+0.85
+80	460.000469	469	+1.02
+85	460.000469	469	+1.02
+20	460.000391	391	+0.85
+10	460.000469	469	+1.02
0	460.000547	547	+1.19
-10	460.000547	547	+1.19
-20	460.000469	469	+1.02
-30	460.000391	391	+0.85

Reference frequency = 460.000000 MHz

**FREQUENCY STABILITY VS. SUPPLY VOLTAGE**

To vary the DC test voltage, a variable DC source was connected to the transmitter, bypassing the battery. The frequency was measured at both the nominal 7.20 V of the battery and at the 85% level or 6.12 V.

With the voltage set to a measurement point, the transmitted signal was captured by a spectrum analyzer and the frequency value determined. The frequencies are compared to the tuned frequency. The data for these measurements are found in Table 3. Again, it can be seen that all values obtained are within the deviation limit of  $\pm 2.5$  ppm or 1150 Hz at the 460 MHz test frequency.

**TABLE 3  
FREQUENCY STABILITY  
VS. SUPPLY VOLTAGE  
460 MHz**

INPUT Volts	Measured Frequency MHz	Dev. Hz	Dev. ppm
7.28 VDC	460.000112	112	+0.243
6.19 VDC	460.000112	112	+0.243

**TRANSIENT STABILITY**

The transient stability measurements indicate the variation in tuned frequency during the brief interval of time during the start of the transmission and at the end of the transmission.

The Model 09001 transmitter was tested for transient frequency behavior using the test method of TIA/EIA-603. A block diagram of the test setup is seen in Fig. 2. A model DCU-1 receiver with an audio bandwidth of 16 kHz (low Pass) was used. The storage oscilloscope was triggered by the radiated signal from the transmitter. Appropriate delay was provided by the digital delay circuitry of the oscilloscope. The 1 kHz test signal was provided by the Marconi signal generator. The generator’s output control was used to insure that the test signal was at least 50 dB below the received signal level from the 09001.

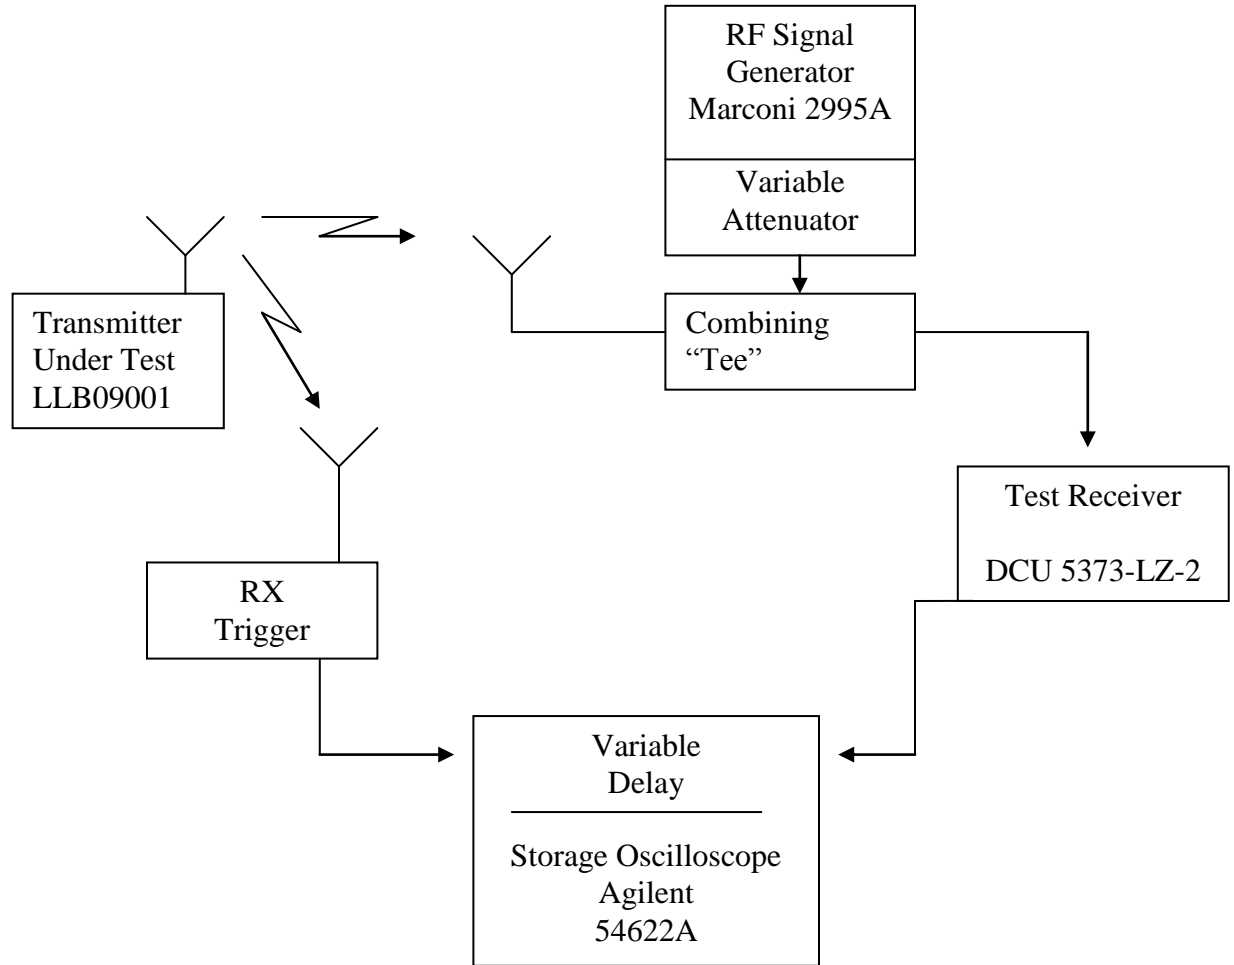

Fig. 2  
Transient Frequency Behavior  
Test Setup

## Test Requirements

The test requirements per 90.214 are:

1. Frequency deviation during  $t_1$  (10 ms duration after  $t_{on}$ ) may be greater than  $\pm 12.5$  kHz because the output power is less than 6 Watts.
2. Frequency deviation during  $t_2$  (25 ms duration after  $t_1$ ) must be less than  $\pm 6.25$  kHz.
3. Frequency deviation after  $t_2$  must be less than  $\pm 2.5$  ppm. or  $\pm 1150$  Hz at 460 MHz.
4. Frequency deviation during  $t_3$  (10 ms duration after transmitter is turned off) may exceed  $\pm 12.5$  kHz because output power is less than 6 Watts.

## Test Data

Figures 3 through 7 show the Model 09001's transient frequency characteristics. The limit masks are indicated on each of the figures.

Fig. 3  $\pm 12.5$  kHz modulated test signal .
