### **TEST REPORT**

### **INTRODUCTION**

The Hexagram Model 10051M is a battery-powered transmitter designed to be connected to a typical utility meter. At programmed intervals the transmitter provides a very short, intermittent radio frequency transmission to provide a remote reading of the meter. A microprocessor provides timing, control and data processing functions. The built in antenna is inaccessible to the user and no provision is made for an external antenna. The version tested has been changed by using a different VCO module and a new RF power amplifier. This report describes the tests performed on the transmitter in support of an application for change.

### **MEASUREMENTS PERFORMED**

Power Output and Spurious Emissions	Page 3
Occupied Bandwidth	Page 9
Frequency Stability vs. Temperature	Page 11
Frequency Stability vs. Supply Voltage	Page 12
Transient Stability	Page 13

<sup>.</sup> The microprocessor portion of the transmitter has been examined for radiated emissions per Part 15, and has been verified to comply with the appropriate sections of that part. The data used for verification of the microprocessor portion is presented in a separate report.

FCC ID: LLB10051M 3 of 17

#### POWER OUTPUT AND SPURIOUS EMISSIONS

A series of measurements of the operating frequencies and any harmonic emissions was made. All measurements below 1 GHz were made on the Smith Electronics 3-meter open area test site located at 8200 Snowville Road, Brecksville, OH. Data pertinent to this site is on file with the FCC (90938) and Industry Canada (4541A-1). The harmonic measurements above 1 GHz were made over a ground plane at a distance of one-meter.. The measurements were made using the substitution method described in TIA/EIA-603-A.

A tuned dipole was used for receiving below 1000 MHz and a wave-guide antenna was used above 1000 MHz. A spectrum analyzer was used as the receiver for both distances.

The transmitter was placed on a remotely rotatable, non-conducting test stand. This general set up is shown in Pictorial 1. Because of the intermittent nature of the normally operating transmitter and its mode of operation, an external battery pack was connected directly to the transmitter and the transmitter was forced to transmit for 10 sec. intervals at a 50% duty rate for the measurements.

With the test receiver tuned to the unmodulated signal, the transmitter under test was rotated to the position of maximum signal. The receiving antenna was then varied between 1 and 4 meters in height to again maximize the signal. Measurements were made with the antennas positioned both vertically and horizontally and the maximum signal recorded.

No differences were observed with different signal detectors, so a peak detector was used for the signals below and above 1000 MHz. Measurements were made with the transmitter tuned to 450 MHz, 460 MHz and 469 MHz. This covers the ends and center of the range to which the transmitter will be tuned in practice.

After the maximum received meter readings were obtained for each frequency and polarity, the transmitter under test was removed from the area and replaced by a transmitting antenna connected to a signal generator. With the transmit antenna placed as close as possible to the position of the test unit, the signal generator was activated at a test frequency. With the signal detected, the receive antenna was positioned vertically for maximum reception. The signal generator output was then adjusted until the received signal was equal to the received signal from the unit under test. These measurements were repeated for each frequency and antenna orientation and the maximum values obtained are noted in Tables 1a – 1c. Transmitting antenna gain and coax loss figures are also included in the Tables.

In order to convert the signal generator output value to equivalent radiated power from a dipole, the following equation is used:

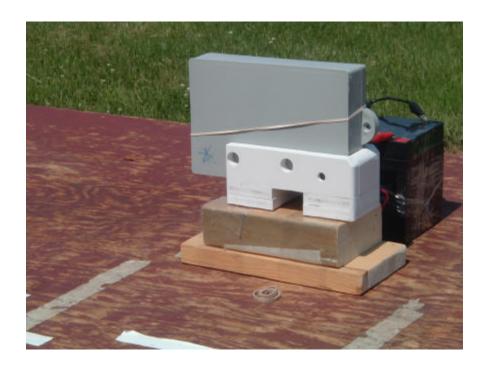

$$P_{\text{d}} = P_{\text{g}} - cable \; loss(dB) + antenna \; gain(dB_{\text{d}}) \label{eq:pd}$$

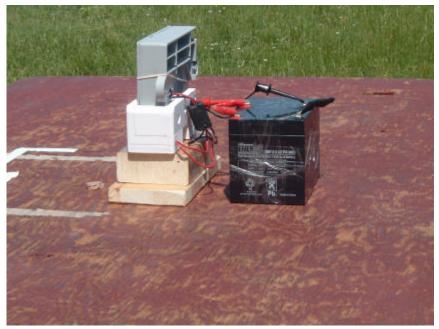

where:

 $P_d$  is the dipole equivalent power,  $P_g$  is the generator output into the substitution antenna and "antenna gain" is the gain of the substitution antenna with respect to a tuned dipole.

According to 90.210(d)(3) all emissions greater than 12.5 kHz from the center of the authorized band shall be attenuated below the unmodulated carrier by  $50 + 10\log(P)$ . Using P = 1.0 W, the required attenuation is 50 dB. An examination of Tables 1a - 1c shows that all emissions are below the required level.

### **OCCUPIED BANDWIDTH**

The emissions close to the center of the specified channel are limited by the emissions masks described in 90.210. For the frequency range of the MTU transmitter, Mask D is specified. From the center frequency of the band  $\pm 5.625$  kHz, 0 dB of attenuation is required. From 5.625 kHz to 12.5 kHz from the center frequency, attenuation must be at least  $7.27(f_d-2.88$  kHz) dB, where  $f_d$  is the displacement frequency from the center of the band in kHz.

At more than 12.5 kHz from the band center, the attenuation must be 70 dB or  $50 + 10 \log(P)$ , whichever is less. Since P was determined to be 1.0 W,  $50 + 10 \log(1.0)$  equals 50 dB.

The plot of Fig. 1 shows the unmodulated carrier (in black), the modulated signal and the emissions mask. The plot indicates that the modulated emission does comply with the requirement for occupied bandwidth as found in 90.210. The unmodulated signal is shifted either high or low by the circuitry. An unmodulated signal is not a normal operating condition.

For purposes of this test, the transmitter was FSK modulated with a continuous sequence of Manchester encoded 1's at the specified 1200 bits per second data rate. The Manchester encoding scheme forces a mid-bit transition for an encoded "1". Therefore, the sequence of continuous 1's sends the highest frequency waveform to the modulator circuit.

### **FREQUENCY STABILITY (Temperature)**

With the transmitter circuit board placed in a non-conducting rack, the temperature stability of the frequency generating components was observed. The transmitter was placed in a temperature chamber, with the battery-powered transmitter set to transmit at intervals of about 40 seconds. A receiving antenna outside the chamber picked up the transmitted signal, which was fed to the real-time analyzer.

With the transmitter programmed to transmit at 460.000000 MHz, the chamber temperature was set to  $20^{\circ}$  C. After reaching the set temperature, the transmitter was allowed to stabilize for about 10 minutes or more. The transmission signal was captured by the real-time analyzer and the frequency was determined. As the unmodulated signal is offset from the tuned frequency, the  $20^{\circ}$  frequency is considered the "standard", and any variation is determined from that frequency. The temperature in the chamber was then changed. At each new temperature, time was allowed for stabilization of the transmitter, a transmission was made and the frequency determined. From  $20^{\circ}$  C, the temperature was increased to  $70^{\circ}$  C, and then lowered in  $10^{\circ}$  C increments to  $-30^{\circ}$  C to cover the required range. The frequency at each temperature was recorded and is found in Table 2. It can be seen from the table that all readings are within the  $\pm 2.5$  ppm allowance ( $\pm 1150$  Hz).

TABLE 2 FREQUENCY STABILITY (TEMPERATURE)

Temperature	Measured Frequency	Dev.	Dev.
° C	MHz	Hz	ppm
+20	460.002344*	0	0
+70	460.002188	-156	0.339

MTU 10051M June 8, 2007

<sup>\*</sup> Reference frequency

FCC ID: LLB10051M 12 of 17

### **FREQUENCY STABILITY (Voltage)**

The frequency stability was also determined as a function of the battery input voltage. With the transmitter set to 460 MHz, a variable transformer was used to set the voltage between about 100% and 85% of the nominal 3.6 VDC input. When the voltage was set to a measurement point, a transmission was captured by the real-time analyzer and the frequency value determined. The data for these measurements are found in Table 3. Again, it can be seen that all values obtained are within the allowed amount of  $\pm 2.5$  ppm or  $\pm 1150$  Hz.

TABLE 3
FREQUENCY STABILITY
(VOLTAGE)

INPUT	Measured Frequency	Dev.	Dev.
DC Volts	MHz	Hz	ppm
	459.998906*	0	0
3.6	459.998906	0	0
3.06	459.998750	-156	0.339

<sup>\*</sup> Reference Value: Determined by initial measured value at 3.6 Volts at room temperature.

### TRANSIENT STABILITY

The transient stability measurements indicate the variation in tuned frequency in the brief interval of time during the start of the transmission and the end of the transmission.

The Model 10051M transmitter was tested for transient frequency behavior using the test method TIA/EIA-603. A block diagram of the test setup is seen in Fig. 2. A Hexagram DCU-1 receiver with an audio bandwidth of 16 kHz (low Pass) was used. The storage oscilloscope was triggered by the radiated signal from the transmitter. Appropriate delay was provided by the digital delay circuitry of the oscilloscope. The 1 kHz test signal was provided by the Marconi signal generator. The generator's output control was used to insure that the signal was at least 50 dB below the received signal level from the 10051M.

### **Test Requirements**

The test requirements per 90.214 are:

- 1. Frequency deviation during  $t_1$  (10 ms duration after  $t_{on}$ ) may be greater than  $\pm 12.5$  kHz because the output power is less than 6 Watts.
- 2. Frequency deviation during  $t_2$  (25 ms duration after  $t_1$ ) must be less than  $\pm 6.25$  kHz.
- 3. Frequency deviation after  $t_2$  must be less than  $\pm 2.5$  ppm. or  $\pm 1150$  Hz at 460 MHz.
- 4. Frequency deviation during  $t_3$  (10 ms duration after transmitter is turned off) may exceed  $\pm 12.5$  kHz because output power is less than 6 Watts.

#### **Test Data**

Figures 3 through 6 show the Model 10051M's transient frequency characteristics. The limit masks are overlaid or indicated on each of the figures.

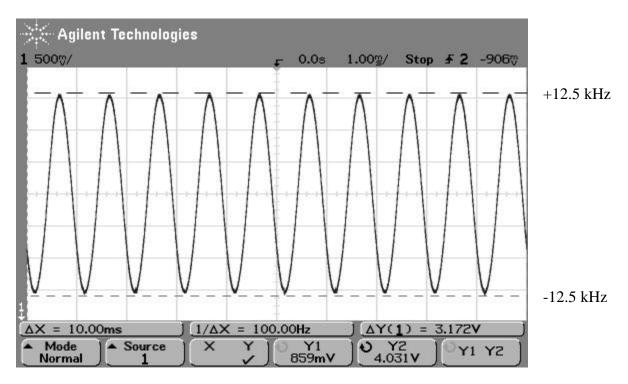

Fig. 3 ±12.5 kHz Signal

 $\pm 12.5 \text{ kHz} = \pm 1.586 \text{ V} = 3.172 \text{ V}$  $\pm 6.25 \text{ kHz} = \pm 0.79 \text{ V} = 1.586 \text{ V}$  $\pm 1150 \text{ Hz} = \pm 146 \text{ mV} = 292 \text{ mV}$
