REF: NEO80-330558 Declared and reported power.

The Power amplifier used in the unit in the downlink direction is described as a 40W and 1W in the uplink. In the downlink direction a single amplifier is used per channel to ensure no intermodulation products occur in the amplification to the power required to overcome combining losses into the antenna system.

In the uplink the 1W amplifiers are used not to produce these levels of power but to ensure good linearity in a multi-carrier environment. It is the third order intercept point we are looking for to ensure the attenuation of unwanted intermodulation products is maximum.

In fact the level of each carrier at the output is limited to 34dBm (2.5W) in the downlink and 3dBm (0.002W) in the uplink this is achieved by automated level control (ALC).

The system is designed to work from a basestation interface and a distributed antenna system.

If you have any further questions or comments do not hesitate to contact me.

Yours faithfully

For and on behalf
