

# **ACE9020**

# **HELPFUL INFORMATION AND ERRATA:**

# 1. ACE9020 Spurious Signals Considerations.

The ACE9020 utilizes an image rejection SSB upconvertor. The image rejection specification for the upconverter is 10 dB min. Typically we measure 20 dB. A good SAW filter should give >35 dB rejection (Toyocom, Murata) typically 45 dB. There may be a need to evaluate different TX filtering in duplexer, the bandstop filter used in many duplexers for the RX frequencies provides no rejection of TX spurii. This would be a requirement for any TX system using an IF with upconversion.

# 2. VHF TANK Circuit component consideration

Low Q tank components especially inductors may result in low TX output power.

The use of Coilcraft part number series 1008CS-xx has resulted in good performance.

# FAQ:

Do you see any problems with using TXPA+ to drive a single-ended rather than double ended and grounding TXPA- through a 1000pF capacitor? Do you have any recommended circuit?

Yes. As the ACE9020 is a differential output grounding one of the outputs will effectively halve the output signal current.

What is the correct control sequence to go from receive (STANDBY) to full duplex?

Control	PD1	PD2	Comments
Sequence			
Standby to			
Duplex:		<u> </u>	
Standby	0	1	
Interim	1	1	The Aux. VCO powers up in this state but the upconverter is off therefore no chance of spurious transmission. The phone must stay in this state until the Aux. VCO is locked, i.e. monitoring lock detect bit in data on serial interface.
Duplex	1	0	Upconvertor now on
Handoff:			
Duplex to Duplex			
Duplex	1	0	
Interim	1	1	Upconvertor off - VHF VCO remains on. Again the PD2 pin should be held high to allow for the main synthesizer to settle.
Duplex	1	0	Upconvertor on - TX output

Note:

PD1, PD2 input current (hi) = 40 uA max.

ACE9030 DOUT 5, 6, 7 specified as 80uA max.

# ACE9020 DATA SHEET

#### **Power Control Circuits**

The inputs PD1 and PD2 are used to select the operating modes as shown below:

PD1	PD2	Mode	
0	0	Sleep	All circuits off
1	0	Standby	Prescaler On
1	1	Transmit Set Up	Prescaler, VHF
0	1	Duplex	oscillator on. Upconverter off All circuits on

The power down inputs (PD1, PD2) are compatible with ACE9030 digital outputs (DO5, 6, 7). These modes allow circuit operation and power consumption to be optimised. The ACE9020 can be put in sleep mode (0, 0) when the power consumption is minimal. The standby mode (1, 0) is used when the phone is in standby (receive only). The prescaler is operational to maintain the main UHF PLL; all circuitry associated with transmit functions is turned off.

There is an intermediate transmit set up state (1, 1). This allows the VHF oscillator and phase locked loop to stabilise before enabling the upconverter, preventing spurious transmissions. The time required for this state will be

determined primarily by the VHF PLL settling time. The bower down inputs can then be set to (0, 1) the full duplex condition. The intermediate state should also be used during a 'handoff' during conversation on an analogue cellular phone, the VHF PLL continuing to operate while the main UHF PLL changer channel, the transmit output being disabled. It is also recommended that the intermediate state is used when going from duplex (0, 1) to standby (1, 0) modes.

#### **Operating Notes**

Good RF layout techniques should be used for this device to obtain optimum performance and also minimise crosstatic between circuit blocks. RF supply decoupling should be provided adjacent to Vcc pins; a value of 27c3 is recommended.

Two external bias resistors are required. A  $22k\Omega$  resistor is connected from BIAS REF (Pin 4) to ground. This sets an accurate reference current for the chip. A further resist on is connected from RSETTXPA (Pin 8) to ground which controls the output level of the VHF oscillator and hence the TXPA output level. The ACE9020 is specified for accurate performance with a value of  $22k\Omega$  for this resistor.

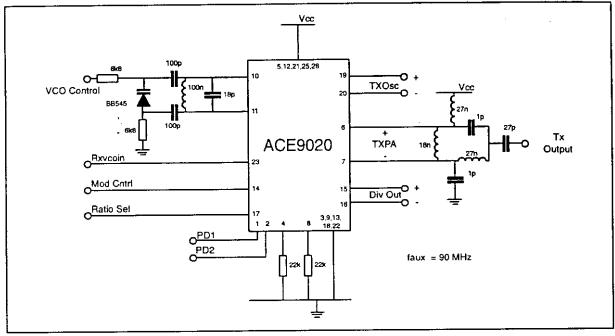

Fig. 3 ACE9020 Test circuit

#### DESCRIPTION

The ACE9020 is designed for use in a transceiver such as an analog cellular phone, which uses an offset modulation transmit architecture. The circuit consists of a VHF voltage controlled oscillator to generate the offset frequency, an upconverter to transmit frequency and also a prescaler for the main UHF phase locked loop. The Rxvcoin signal to the ACE9020 is normally the UHF local oscillator used for downconversion.

A basic block diagram is shown in fig. 2, further information on external connections is provided in the test circuit (fig. 3) and the applications diagram (fig. 4).

# **VHF Oscillator**

This oscillator is a differential design which uses an external tank circuit as shown in fig. 3 and fig. 4. The components shown in fig. 3 give a VCO frequency of 90MHz. A varactor diode is coupled capacitively to the tank circuit; the anode is referenced to ground via a resistor. The VCO control from a synthesiser (eg ACE9030) charge pump output is applied to the cathode of the varactor also through a resistor. These resistors should be the same value to keep the differential circuit balanced. The VCO gain with the components shown will be typically 2 MHz/V. Modulation is applied to the anode via a resistive divider as shown in fig. 4; the actual signal applied to the varactor will be small as the frequency deviation will typically be a maximum of 12kHz in many applications. Differential buffered outputs from the oscillator (TXOSC) interface directly to the ACE9030 auxiliary synthesier inputs.

#### Upconverter

An image reject mixer is used for the upconversion. This provides typically 20dB rejection of the unwanted upper sideband. The quadrature networks for the mixer are all provided on chip; this is optimised for UHF local oscillator and VHF offset oscillator frequencies typically used for analog cellular phones on the AMPS and TACS systems. Further

filtering of the TXPA output will be required to provide further suppression of the unwanted upper sideband, local oscillator signal and harmonics to meet cellular telephone specifications. SAW filters are available for the various transmit frequency bands.

The upconverter outputs (TXPA + and -) are differential current outputs. The use of differential outputs minimises current switching within the device and thus minimise crosstalk to other circuit blocks. The TXPA outputs must be matched to the external filter, normally  $50\Omega$  and single-ended. The network shown in fig. 3 provides a transformation from  $400\Omega$  differential to  $50\Omega$  single-ended and also provides dc bias from the Vcc supply to the open collector TXPA outputs. This network provides plus and minus  $90^\circ$  phase shift in each output which are then summed. Alternatively a Balun transformer could be used, it will again be necessary to provide dc bias to the TXPA outputs. The load to the current outputs should be maximised to obtain the maximum power output;  $400\Omega$  is an optimum figure as higher values require impractical component values for matching.

#### Prescaler

The two modulus prescaler is part of the UHF phase locked loop. It will typically be operating with ACE9030 radio interface and synthesiser. There is also a choice of divider ratio, set by the ratio select input as shown in table. 1, below.

	Ratio Sel = LOW	Ratio Sel = HIGH
Mod_Cntrl = LOW	+129	÷65
Mod_Cntrl = HIGH	+128	+64

Table. 1

The differential divider outputs can be directly coupled to the ACE9030 main synthesiser inputs.

# ACE9020 RECEIVER AND TRANSMITTER INTERFACE

(Supersedes October 1996 edition DS4287 - 2.3)

ACE9020 is a VHF oscillator, up-converter and prescaler. It is used in an offset modulated transmit architecture where a UHF synthesiser makes the channel selection and a second synthesiser generates a fixed transmit offset.

A VCO signal from ACE9010 at UHF drives a buffer in ACE9020 to feed an on-chip prescaler and transmit upconverter. The prescaler is a dual two-modulus divider and drives the main synthesiser input of the ACE9030. The SSB up-converter suppresses the unwanted transmit sideband.

The VHF oscillator is buffered to drive the auxiliary synthesiser input of the ACE9030 and is locked to the offset frequency. This frequency is modulated by varying the resonant frequency of the external tank circuit. Both this oscillator and the UHF VCO drive the up-converting mixer to generate the transmit signal.

Various power saving modes for battery economy are included. These allow the transmit sections to be shut down during stand-by and the whole chip can be shut down during sleep mode. The circuit techniques used have been chosen to minimise external components and at the same time give very high performance.

#### **FEATURES**

- Low Power Low Voltage (3.6 to 5.0 V) Operation
- Power Down Modes
- Differential Signals to Minimise Cross-talk
- Auxiliary Oscillator with Transmit Up-converter
- Prescaler for Main Synthesiser
- Part of the ACE Integrated Cellular Phone Chipset
- Small Outline 28 pin Package

#### **APPLICATIONS**

- AMPS and TACS Cellular Telephone
- Two-Way Radio Systems

#### **RELATED PRODUCTS**

ACE9020 is part of the following chipset:

- ACE9010 R.F. Front End with VCO
- ACE9030 Radio Interface and Twin Synthesiser
- ACE9040 Audio Processor
- ACE9050 System Controller and Data Modem
