MEASUREMENT PROCEDURE:

1. The transmitter carrier output frequencies are 928.050, 943.950, and 952.950. The reference oscillator frequency is 23.04 MHz. The power amplifier has voltage levels at 14.0 Volts and 8.0 Volts for 10 watts and 1 watt, respectively.
2. The carrier reference was established on the spectrum analyzer with the filter bypass in place. Then the spectrum was scanned from DC to $2 F_c$. Finally, the high pass filter was inserted to null the carrier fundamental and extend the range of the spectrum analyzer for harmonic measurements above $2 F_c$.
3. At each spurious frequency, generation substitution was used to establish the true spurious level.
4. The spectrum was scanned to the 10th harmonic of the highest internally generated frequency.

Necessary Bandwidth Measurement

This radio modem uses digital modulation signals, passing through a Squared Root Raised Cosine $\alpha=0.2$ or $\alpha=0.5$ DSP implemented low-pass filter to an FM transceiver. The digital modulation is based on SRRC4FSK allows a SRRC2FSK subset to be used for lower bit rate with a better sensitivity reception. The necessary bandwidth calculation for this type of modulation is not covered by paragraphs (1), (2) or (3) from 2.202(c). Therefore, the approach outlined in (2.202(c)(4)) is applicable in this case.

The measurement explanations are provided below.

THEORY OF MEASUREMENT

The way to define the Occupied Bandwidth is “the frequency bandwidth such that, below its lower and above its upper frequency limits, the mean powers radiated are each equal to 0.5 percent of the total mean power radiated by a given emission” (FCC 2.202), the mathematics are as follows:

$$0.005*TP=P_{(f_1)}=\int_0^{f_1} PSD_{(f)}df$$

$$0.995*TP=P_{(f_2)}=\int_0^{f_2} PSD_{(f)}df$$

$$OBW=f2-f1$$

where TP (total mean power) is

$$TP= \int_0^{+\infty} PSD(f)df = (1/t) \int_{-\infty}^{+\infty} |z(t)|^2 dt$$

and PSD (power spectral distribution) is

$$PSD(f)=|Z(f)|^2+|Z(-f)|^2 \quad 0 \leq f < \infty$$

and expresses the positive frequency representation of the transmitter output power for z(t) signal.

By applying these mathematics to the measurements, it is possible to measure the Occupied Bandwidth using a digital spectrum analyzer.

The Occupied Bandwidth measurement is in two parts relatively independent of each other. The first gives the RF spectrum profile, and the second calculates the frequency limits and they result in the Occupied bandwidth. While the first involves RF measurement instrumentation, the second is strictly a computational part related to measured trace.

TEST EQUIPMENT:

- 50-Ohm Attenuator, Bird Electronics Model 50-A-FFN-20 (20dB, 50W)

- Modulation Analyzer, Hewlett Packard Model HP8901A

TEST SET-UP:

For the above requirements, the occupied bandwidth of a transmitter was measured using an HP8563E using the following settings:
 Occupied BW % Power: 99%
 Trace: Max Hold A
 RBW: 100 Hz (6.25 and 12.5 kHz channels)
 RBW: 300 Hz (25 kHz and 50 kHz channels)
 VBW: 3 kHz

 SPAN: 150 kHz (25 kHz channels)
 SPAN: 200 kHz (50 kHz channels)

MODULATION SOURCE DESCRIPTION:

The 4-level signaling transmits two information bits per symbol (baud), which yields a bit rate of twice the on-air baud rate. Hence the 64 kbps references in the Installation Guide correspond to a transmitter baud rate of 32000 baud. The 8-level signaling transmits three information bits per symbol (baud), which yields a bit rate of three times the on-air baud rate. Hence the 12, 24, 48, or 96 kbps references in the Installation Guide correspond to a transmitter baud rate of 4000,

8000, 16000 or 32000 baud. The 16-level signaling transmits four information bits per symbol (baud), which yields a bit rate of four times the on-air baud rate. Hence the 16, 32, 64, or 128 kbps references in the Installation Guide correspond to a transmitter baud rate of 4000, 8000, 16000 or 32000baud. That digital signal is digitally filtered (Square Root Raised Cosine pulse shaping with $\alpha=0.2$ or 0.5) by the DSP and converted to I&Q components, then fed to the digital to analog converter. This SRRC4FSK, SRRC8FSK, or SRRC16FSK wave shape applied to the FM modulator will then produce a compact RF spectrum, when using proper frequency deviation, to fit inside the restrictive masks inherent to the intended channel bandwidth.

TX Data Test Pattern:

The transmit "test data" pattern command produces a 107,3741,823 bit pseudo- random pattern. This pattern is generated by the DSP. The 107,3741,823 bit sequence is repeated thereafter as long is necessary to complete the test duration, this sequence lasts 67,109 seconds at 16 kbps. Commonly this is longer than the test duration. This pattern is applied to the DSP modulator for mapping to 4-FSK, 8-FSK and 16-FSK and pulse shaping with SRRC $\alpha=0.2$ or $\alpha=0.5$ depending on the channel selection. This data follows same modulation process as described in MODULATION SOURCE DESCRIPTION and the resulting base band signal feeds the modulator's input of the transceiver.
