#### 4 Summary

#### Summary of test results

The tested sample complies with the requirements set forth in the

Code of Federal Regulations CFR 47, Part 15, Sections 15.205, 15.207, 15.209, 15.215 and 15.225

of the Federal Communication Commission (FCC).

## 5 Operation Mode and Configuration of EUT

#### **Operation Mode(s)**

The EUT is transmitting continuously and read out TAG with KABA test software.

#### Configuration(s) of EUT

The EUT is connected via USB to test notebook

| List o | List of ports and cables |                             |            |              |  |

#### 6 Measurement Procedures

#### 6.1 Bandwidth Measurements

| Measurement Procedure:   |   |  |  |
|--|---|--|--|
| Rules and specifications:  | CFR 47 Part 2, section 2.202(a)<br>CFR 47 Part 15, section 15.215(c)<br>ANSI C63.10, section 6.9.1                  |  |  |
| Guide:   | ANSI C63.10   |  |  |
| Measurement setup:   | <ul> <li>☐ Conducted: See below</li> <li>☑ Radiated: Radiated Emission Measurement 9 kHz to 30 MHz (6.3)</li> </ul> |  |  |
| If antenna is detachable bandwidth measurements shall be performed at the antenna connector (conducted measurement) when the transmitter is adjusted in accordance with the tune-up procedure, if applicable. The RF output terminals are connected to a spectrum analyzer. If required, a resistive matching network equal to the impedance specified or employed for the antenna is used as well as dc block and appropriate attenuators (50 Ohms). The electrical characteristics of the radio frequency load attached to the output terminals shall be |   |  |  |

stated, if applicable.

If radiated measurements are performed the same test setups and instruments are used as with radiated emission measurements for the appropriate frequency range.

The analyzer settings are specified by the test description of the appropriate test record(s).

Test instruments used for conducted measurements:

#### 6.2 Conducted AC Powerline Emission

| Measurement Procedure:    |                                |  |  |
|---------------------------|--------------------------------|--|--|
| Rules and specifications: | CFR 47 Part 15, section 15.207 |  |  |
| Guide:                    | ANSI C63.10 / CISPR 22         |  |  |

Conducted emission tests in the frequency range 150 kHz to 30 MHz are performed using Line Impedance Stabilization Networks (LISNs). To simplify testing with quasi-peak and average detector the following procedure is used:

First the whole spectrum of emission caused by the equipment under test (EUT) is recorded with detector set to peak using CISPR bandwidth of 10 kHz. After that all emission levels having less margin than 10 dB to or exceeding the average limit are retested with detector set to quasi-peak.

If average limit is kept with quasi-peak levels no additional scan with average detector is necessary. In cases of emission levels between quasi-peak and average limit an additional scan with detector set to average is performed.

According to ANSI C63.10, testing of intentional radiators with detachable antenna shall be performed using a suitable dummy load connected to the antenna output terminals. Otherwise, the tests shall be made with the antenna connected and, if adjustable, fully extended.

Testing with dummy load may be necessary to distinguish (unintentional) conducted emissions on the supply lines from (intentional) emissions radiated by the antenna and coupling directly to supply lines and/or LISN. Usage of dummy load has to be stated in the appropriate test record(s) and notes should be added to clarify the test setup.

## 6.3 Radiated Emission Measurement 9 kHz to 30 MHz

| Measurement Procedure:    |  |  |  |  |  |
|---------------------------|--|--|--|--|--|
| Rules and specifications: | CFR 47 Part 15, sections 15.205, 15.215(b) and 15.225(a)-(d) |  |  |  |  |
| Guide:                    | ANSI C63.10  |  |  |  |  |

Radiated emission in the frequency range 9 kHz to 30 MHz is measured using an active loop antenna. First the whole spectrum of emission caused by the equipment is recorded at a distance of 3 meters in a fully or semi anechoic room with the detector of the spectrum analyzer or EMI receiver set to peak. This configuration is also used for recording the spectrum of intentional radiators.

Hand-held or body-worn devices are rotated through three orthogonal axes to determine which attitude and configuration produces the highest emission relative to the limit and therefore shall be used for final testing.

EUT is rotated all around to find the maximum levels of emissions. Equipment and cables are placed and moved within the range of position likely to find their maximum emissions.

If worst case emission of the EUT cannot be recorded with EUT in standard position and loop antenna in vertical polarization the EUT (or the radiating part of the EUT) is rotated by 90 degrees instead of changing the loop antenna to horizontal polarization. This procedure is selected to minimize the influence of the environment (e.g. effects caused by the floor especially with longer distances).

Final measurement is performed at a test distance D of 30 meters using an open field test site. In case the regulation requires testing at other distances, the result is extrapolated by either making measurements at an additional distance D of 10 meters to determine the proper extrapolation factor or by using the square of an inverse linear distance extrapolation factor (40 dB/decade). In cases of very low emissions measurements are performed at shorter distances and results are extrapolated to the required distance. The provisions of CFR 47 Part 15 sections 15.31(d) and (f)(2) apply. According to CFR 47 Part 15 section 15.209(d) final measurement is performed with detector function set to quasi-peak except for the frequency bands 9 to 90 kHz and 110 to 490 kHz where, for non-pulsed operation, average detector is employed.

If the radiated emission limits are expressed in terms of the average value of the emission there also is a peak limit corresponding to 20 dB above the maximum permitted average limit. Additionally, if pulsed operation is employed, the average field strength is determined by averaging over one complete pulse train, including blanking intervals, as specified in CFR 47 Part 15 section 15.35(c). If the pulse train exceeds 0.1 second that 0.1 second interval during which the value of the emission is at its maximum is selected for calculation. The pulse train correction is added to the peak value of the emission to get the average value.

### 6.4 Radiated Emission in Fully or Semi Anechoic Room

| Measurement Procedure:    |  |
|---------------------------|--|
| Rules and specifications: | CFR 47 Part 15, sections 15.205(b) and 15.225(d) |
| Guide:                    | ANSI C63.10                                      |
|                           |  |

Radiated emission in fully or semi anechoic room is measured in the frequency range from 30 MHz to the maximum frequency as specified in CFR 47 Part 15 section 15.33.

Measurements are made in both the horizontal and vertical planes of polarization using a spectrum analyzer with the detector function set to peak and resolution as well as video bandwidth set to 100 kHz (below 1 GHz) or 1 MHz (above 1 GHz).

Testing up to 1 GHz is performed with a linear polarized logarithmic periodic antenna combined with a 4:1 broadband dipole ("Trilog broadband antenna"). For testing above 1 GHz horn antennas are used.

All tests below 8.2 GHz are performed at a test distance D of 3 meters. For higher frequencies the test distance may be reduced (e.g. to 1 meter) due to the sensitivity of the measuring instrument(s) and the test results are calculated according to CFR 47 Part 15 section 15.31(f)(1) using an extrapolation factor of 20 dB/decade. If required, preamplifiers are used for the whole frequency range. Special care is taken to avoid overload, using appropriate attenuators and filters, if necessary.

If the radiated emission limits are expressed in terms of the average value of the emission there also is a peak limit corresponding to 20 dB above the maximum permitted average limit. Additionally, if pulsed operation is employed, the average field strength is determined by averaging over one complete pulse train, including blanking intervals, as specified in CFR 47 Part 15 section 15.35(c). If the pulse train exceeds 0.1 second that 0.1 second interval during which the value of the emission is at its maximum is selected for calculation. The pulse train correction is added to the peak value of the emission to get the average value.

Hand-held or body-worn devices are rotated through three orthogonal axes to determine which attitude and configuration produces the highest emission relative to the limit and therefore shall be used for final testing.

During testing the EUT is rotated all around to find the maximum levels of emissions. Equipment and cables are placed and moved within the range of position likely to find their maximum emissions.

For final testing below 1 GHz a semi anechoic room complying with the NSA requirements of ANSI C63.10 for alternative test sites is used (see 6.5). If prescans are recorded in fully anechoic room they are indicated appropriately.

Fully or semi anechoic room

Additionally, if pulsed operation is employed, the average field strength is determined by averaging over one complete pulse train, including blanking intervals, as specified in CFR 47 Part 15 section 15.35(c). If the pulse train exceeds 0.1 second that 0.1 second interval during which the value of the emission is at its maximum is selected for calculation. The pulse train correction is added to the peak value of the emission to get the average value. |  |  |  |  |  |
| Hand-held or body-worn devices are tested in the position producing the highest emission relative to the limit as verified by prescans in fully anechoic room. |  |  |  |  |  |  |
| spectrum of emission caused by<br>table position, antenna height a<br>Data reduction is applied to the   | c room is used first a peak scan is performed in four positions to get the whole<br>y EUT with the measuring antenna raised and lowered from 1 to 4 m to find<br>nd antenna polarization for the maximum emission levels.<br>se results to select those levels having less margin than 10 dB to or exceeding<br>mited number of maximums. Further maximization is following.   |  |  |  |  |  |

With detector of the test receiver set to quasi-peak final measurements are performed immediately after frequency zoom (for drifting disturbances) and maximum adjustment.

Equipment and cables are placed and moved within the range of position likely to find their maximum emissions.

In cases where prescans in a fully anechoic room are taken (e. g. if EUT is operating for a short time only or battery is dircharged quickly) final measurements with quasi-peak detector are performed manually at frequencies indicated by prescan with EUT rotating all around and receiving antenna raising and lowering within 1 meter to 4 meters to find the maximum levels of emission.

Equipment and cables are placed and moved within the range of position likely to find their maximum emissions.

For measuring emissions of intentional radiators and receivers a test distance D of 3 meters is selected. Testing of unintentional radiators is performed at a distance of 10 meters. If limits specified for 3 meters shall be used for measurements performed at 10 meters distance the limits are calculated according to CFR 47 Part 15 section 15.31(d) and (f)(1) using an inverse linear-distance extrapolation factor of 20 dB/decade.

Alternate test site (semi anechoic room)

## 6.6 Carrier Frequency Stability

| Measurement Procedure:    |                                   |  |  |  |
|---------------------------|-----------------------------------|--|--|--|
| Rules and specifications: | CFR 47 Part 15, section 15.225(e) |  |  |  |
| Guide:                    | ANSI C63.10                       |  |  |  |

The frequency tolerance of the carrier signal is measured over a temperature variation of -20 °C to +50 °C at normal supply voltage, and for a variation in the primary supply voltage from 85% to 115% of the rated supply voltage at a temperature of 20 °C.

If the EUT provides an antenna connector the spectrum analyzer is connected to this port. If required, a resistive matching network equal to the impedance specified or employed for the antenna is used as well as dc block and appropriate attenuators (50 Ohms). In cases where the EUT does not provide an antenna connector a test fixture is used.

For battery operated equipment, the test is performed using a new battery. Alternatively, an external supply voltage can be used and is at least set to:

- the maximum battery voltage as delivered by a new battery or 115% of the battery nominal voltage
- the battery nominal voltage
- 85% of the battery nominal voltage
- the battery operating end point voltage which shall be specified by the equipment manufacturer

The EUT is operating providing an unmodulated carrier. The peak detector of the spectrum analyzer is selected and resolution as well as video bandwidth are set to values appropriate to the shape of the spectrum of the EUT. The frequency counter mode of the spectrum analyzer is used to maximize the accuracy of the measured frequency tolerance.

If an unmodulated carrier is not available a significant and stable point on the spectrum is selected and the span is reduced to a value that delivers an accuracy which shall be better than 1% of the maximum frequency tolerance allowed for the carrier signal. This method may be performed as long as the margin to the frequency tolerance allowed is larger than the uncertainty of the measured frequency tolerance.

## 8.1 Occupied Bandwidth

| Rules and specifications: | CFR 47 Part 2, section 2.202(a)  |                              |  |
|---------------------------|--|------------------------------|--|
| Guide:                    | ANSI C63.10  | ANSI C63.10                  |  |
| Description:              | The occupied bandwidth according to CFR 47 Part 2, section 2.202(a), is measured as the 99% emission bandwidth, i.e. below its lower and above its upper frequency limits, the mean powers radiated are each equal to 0.5% of the total mean power radiated by a given emission. |                              |  |
|                           | The occupied bandwidth according to ANSI C63.10; is measured as the frequency range defined by the points that are 26 dB down relative to the maximum level of the modulated carrier.  |                              |  |
|                           | The resolution bandwidth of the spectrum analyzer shall be set to a value greater than 5.0% of the allowed bandwidth. If no bandwidth specifications are given, the following guidelines are used:   |                              |  |
|                           | Fundamental frequency  | Minimum resolution bandwidth |  |
|                           | 9 kHz to 30 MHz  | 1 kHz                        |  |
|                           | 30 MHz to 1000 MHz   | 10 kHz                       |  |
|                           | 1000 MHz to 40 GHz   | 100 kHz                      |  |
|                           | The video bandwidth shall be at least three times greater than the resolution bandwidth.   |                              |  |
| Measurement procedure:    | Bandwidth Measurements (6.1)   |                              |  |
|                           |  |                              |  |

| Occupied Bandwidth (99 %): | 838 kHz |
|----------------------------|---------|
|----------------------------|---------|

#### 8.2 Bandwidth of the Emission

| Rules and specifications: | CFR 47 Part 15, section 15.215(c)   |
|---------------------------|---|
| Guide:                    | ANSI C63.10   |
| Description:              | The 20 dB bandwidth of the emission is measured as the frequency range defined by the points that are 20 dB down relative to the maximum level of the modulated carrier. For intentional radiators operating under the alternative provisions to the general emission limits the requirement to contain the 20 dB bandwidth of the emission within the specified frequency band includes the effects from frequency sweeping, frequency hopping and other modulation techniques that may be employed as well as the frequency stability of the transmitter over expected variations in temperature and supply voltage. If a frequency stability is not specified in the regulations, it is recommended that the fundamental emission be kept within at least the central 80% of the permitted band in order to minimize the possibility of out-of-band operation. |
|                           | The span range of the spectrum analysator display shall be between two<br>times and five times of the occupied bandwidth. The resolution bandwidth<br>of the spectrum analyzer should be approximately 1 % to 5 % of the<br>occupied bandwidth, unless otherwise specified, depending on the<br>applicable requirement. The video bandwidth shall be at least three times<br>greater than the resolution bandwidth. The dynamic range of the<br>spectrum analyzator at the selected resolution bandwidth shall be more<br>than 10 dB below the target "dB down" (attenuation) requirement.<br>The video bandwidth shall be at least three times greater than the<br>resolution bandwidth.   |

## Sample calculation of final values:

| Final Value (dBµV/m) | = | Reading Value (dBµV) + Correction Factor (dB/m) |
|----------------------|---|---|
|                      |   | + Pulse Train Correction (dB)                   |

# 8.8 Carrier Frequency Stability

| Rules and specifications: | CFR 47 Part 15, section 15.225(e)   |  |  |
|---------------------------|---|--|--|
| Guide:                    | ANSI C63.10   |  |  |
| Limit:                    | The frequency tolerance of the carrier signal shall be maintained within $\pm 0.01$ % ( $\pm 100$ ppm) of the carrier frequency under nominal conditions. |  |  |
| Temperature range:        | -20°C to +50°C (at normal supply voltage)   |  |  |
| Voltage range:            | 85% to 115% of the rated supply voltage (at a temperature of +20°C)   |  |  |
| Measurement procedure:    | Carrier Frequency Stability (6.6)   |  |  |
|                           |   |  |  |
| Comment:                  |   |  |  |
| Date of test:             | 2015-03-11  |  |  |

## 8.8.1 Carrier Frequency Stability vs. Temperature

Note 1: No calibration required.

Note 2: Not calibrated separately but with the whole test system when recording calibration data.

Note 3: No calibration required. Devices are checked before use.

Note 4: No calibration required. Devices are checked by calibrated equipment during test.
