Re: **Submitting Attachments for TDMA Phone FCC ID: NWJ10A001A and Confirmation #: EA94679**

To Whom It May Concern:

The accompanying SAR documents are additions to the basic submission. The Panasonic TDMA phone operates in dual modes (AMPS and TDMA) and dual bands (835 MHz and 1900 MHz). In addition the phone can be used in two manners:

1. Against the side of the head as a regular handset
2. In a case with a belt clip intended to be attached to the belt and a headset for hands-free operation

The handset was tested in the regular hand-held position against the head in all three modes of operation (835MHz AMPS, 835MHz TDMA and 1900MHz TDMA). The maximum 1g SAR for each of these modes was found to be:

1. 835MHz AMPS      1.436 W/kg
2. 835MHz TDMA      0.577 W/kg (estimated from 1. above and the ratio of peak local SARs in section 6.2.4 of the Project #: MATB-EBTX110A-3252B report)
3. 1900 TDMA      1.241 W/kg

The worst of these (835 AMPS) was then explored with muscle tissue to simulate the body worn hands-free mode. Both sides of the handset at high, middle and low frequencies were checked and the worst of these six was parametrically investigated as a function of separation between the handset and the phantom. A 1g SAR of 1.5 W/kg was determined to occur at 11mm from the body. Since the manufacturer supplied case and belt clip puts the handset 25mm from the body, this configuration also passes the FCC 96-326 requirement.

The documents added are (all in PDF format):

1. FINAL SAR report for PANASONIC BRAIN.pdf (Project #: MATB-EBTX110A-3252B)
2. FINAL SAR report for PANASONIC BODY.pdf (Project #: MATB-EBTX110A-3252M)
3. 31-SSI\_DRB\_TP\_D01\_031Ver5.PDF (Phantom Design Requirements)
4. 32-SSI\_DRB\_TP\_D01\_032Rev4.PDF (Probe Design and Calibration Requirements)

5. 33-SSI\_DRB\_TP\_D01\_033Ver4.PDF (Tissue Recipe and Calibration Requirements)
6. 34-SSI\_DRB\_TP\_D01\_034Ver2.PDF (Positioning and Scanning Requirements)

If you have problems opening any of these documents please contact Dr. Paul G. Cardinal as soon as possible to rectify the situation. Dr. Cardinal can be reached at:

## ENGINEERING SUMMARY

This report contains the results of the engineering evaluation performed on a dual-mode dual-band TDMA phone (835 MHz AMPS, 835 MHz TDMA and 1900 MHz TDMA). The measurements were carried out in accordance with FCC 96-326. The dual-mode dual-band TDMA phone was evaluated for its maximum power level in each mode and band.

The phone was tested at high, middle, and low frequencies, for both bands, and both modes, with the maximum SAR coinciding with the peak performance RF output power of channel 991 (low, 824 MHz), in the AMPS mode. Test data and graphs are presented in this report.

This unit as tested, and as it will be marketed and used is found to be compliant with the FCC 96-326 requirement, for an uncontrolled RF exposure environment.

## 1. INTRODUCTION

Tests were conducted to determine the Specific Absorption Rate (SAR) of a sample of a Panasonic TDMA phone. These tests were conducted at APREL Laboratories' facility located at 51 Spectrum Way, Nepean, Ontario, Canada. A view of the SAR measurement setup can be seen in Appendix A Figure 1. This report describes the results obtained.

## 2. APPLICABLE DOCUMENTS

The following documents are applicable to the work performed:

- 1) FCC 96-326, Guidelines for Evaluating the Environmental Effects of Radio-Frequency Radiation
- 2) ANSI/IEEE C95.1-1992, IEEE Standard for Safety Levels with Respect to Human Exposure to Radio Frequency Electromagnetic Fields, 3 kHz to 300 GHz.
- 3) ANSI/IEEE 95.3-1992, IEEE Recommended Practice for the Measurement of Potentially Hazardous Electromagnetic Fields – RF and Microwave.
- 4) OET Bulletin 65 (Edition 97-01) Supplement C (Edition 97-01), "Evaluating Compliance with FCC Guidelines for Human Exposure to Radio Frequency Electromagnetic Fields".

## 3. EQUIPMENT UNDER TEST

- Panasonic model EB-TX110A dual-mode dual-band TDMA phone s/n p6.0 #35
- Panasonic headset
- Panasonic break-out box, revision 3 (used for handset configuration and RF conducted power measurements)
- Magitronic laptop, s/n 015600T08338 (used for handset configuration and RF conducted power measurements)

The antenna is a fixed stub antenna and is located on the left-hand side of the top of the handset. Please refer to Appendix B for photographs of the antenna. The axis of the antenna is 19 mm from the front surface plane of the handset and 19.5 mm from the back surface plane of the handset with a high capacity battery attached.

#### 4. TEST EQUIPMENT

- Narda 8021B miniature E-field probe, s/n 04007, Asset # 301339
- CRS Robotics A255 articulated robot arm, s/n RA2750, Asset # 301355
- CRS Robotics C500 robotic system controller, s/n RC584, Asset # 201354
- HP 438A power meter, s/n 2502A01684, Asset # 301417
- APREL UH-1, Universal Head-Arm, s/n 001, Asset # 301376
- Tissue Recipe and Calibration Requirements, APREL procedure SSI/DRB-TP-D01-033

#### 5. TEST METHODOLOGY

1. The test methodology utilised in the certification of the dual-mode dual-band TDMA phone complies with the requirements of FCC 96-326 and ANSI/IEEE C95.3-1992.
2. The E-field is measured with a small isotropic probe (output voltage proportional to  $E^2$ ).
3. The probe is moved precisely from one point to the next using the robot (10 mm increments for wide area scanning, 5 mm increments for zoom scanning, and 2.5 mm increments for the final depth profile measurements).
4. The probe travels in the homogeneous liquid simulating human tissue. Appendix D contains information about the recipe and properties of the simulated tissue used for these measurements.
5. The liquid is contained in a manikin simulating a portion of the human body.
6. The TDMA phone is positioned in a normal usage position.

7. All tests were performed with the highest power available from the sample dual-mode dual-band TDMA phone, under transmit conditions.

More detailed descriptions of the test method is given in Section 6 when appropriate.

## 6. TEST RESULTS

### 6.1. TRANSMITTER CHARACTERISTICS

The battery-powered transmitter will consume energy from its batteries, which may affect its transmission characteristics. In order to gage this effect the output of the transmitter is sampled before and after each SAR run. In the case of the Panasonic dual-mode dual-band TDMA phone, which has an externally accessible feedpoint, the conductive power was measured. A power meter was connected directly to the device via cable. The following table shows the difference between the sampled power before and after each of the six sets of data used for the worst case SAR used in this report. (The device was operating in the AMPS mode in the 835 MHz band, for the worst case SAR.)

Scan		Relative Power Reading (dB)			Battery #
Type	Height (mm)	Before	After	$\Delta$	
Area	2.5	10.20	10.07	-0.13	4
Area	12.5	10.83	10.18	-0.65	8
Zoom	2.5	10.91	10.30	-0.61	5
Zoom	7.5	10.83	10.34	-0.49	12
Zoom	12.5	10.77	10.11	-0.66	11
Depth	2.5 – 17.5	10.85	10.14	-0.71	5

**Note:** the adapter cable loss of 1.6 dB has not been incorporated into these measurements, nor the 13 dB attenuation pad, nor the 0.55dB RF power sensor correction factor (total of 15.15dB).

## 6.2. SAR MEASUREMENTS

1. RF exposure is expressed as a Specific Absorption Rate (SAR). SAR is calculated from the E-field, measured in a grid of test points as shown in Appendix A Figure 2. SAR is expressed as RF power per kilogram of mass, averaged in 1 gram of tissue.
2. The Panasonic dual-mode dual-band TDMA phone was put into test mode for the SAR measurements via a laptop and break-out box interface (manufacturer supplied) to control the mode, channel and operating power. The phone was initially set to operate in the AMPS mode on channel 991 (low, 824 MHz) and its maximum operating power (nominally 375 mW, 25.74dBm).
3. Figure 3 in Appendix A shows a contour plot of the SAR measurements for the sample Panasonic dual-mode dual-band TDMA phone operating on the low channel. The presented values were taken 2.5 mm into the simulated tissue from the Universal Head-Arm's (UH-a) solid inner surface. Figure 2 in Appendix A shows the UH-a used in the measurements, with its arm in position to hold the dual-mode dual-band TDMA phone against the composite ear. The top of the phone is aligned with the top of the composite pinna of the UH-a, and the microphone is aligned with the line of the mouth. A grid is shown inside of the head indicating the orientation of the x-y grid used, with the origin (0,0) at the top of the pinna. The x-axis is positive towards the left (the mouth) and the y-axis is positive towards the bottom (the left eye).

A different presentation of the same data is shown in Appendix A Figure 4. This is a surface plot, where the measured SAR values provide the vertical dimension, which is useful as a visualisation aid.

Similar data was obtained 12.5 mm into the simulated tissue. These measurements are presented as a contour plot in Appendix A Figure 5 and surface plot in Figure 6.

Figure 7 in Appendix A shows an overlay of the TDMA phone, superimposed onto a contour plot similar to that shown in Figure 3.

Figures 3 through 6 in Appendix A show that there is a dominant peak, in the contour plots, that diminishes in magnitude with depth into the tissue simulation.

4. Wide area scans were performed for the low, middle and high channels of the AMPS and 800 MHz TDMA modes, both on channels 991, 384 and 798 respectively, as well as in the 1900 MHz TDMA mode, channels 2, 998 and 1998 respectively.

Mode	Channel	Channel #	Frequency (MHz)	Peak Single Point SAR (W/kg)
AMPS	Low	991	824.07	0.92
AMPS	Middle	384	836.52	0.80
AMPS	High	798	848.97	0.90
TDMA-800	Low	991	824.07	0.37
TDMA-800	Middle	384	836.52	0.30
TDMA-800	High	798	848.97	0.32
TDMA-1900	Low	2	1850	0.60
TDMA-1900	Middle	998	1880	0.71
TDMA-1900	High	1998	1910	0.44

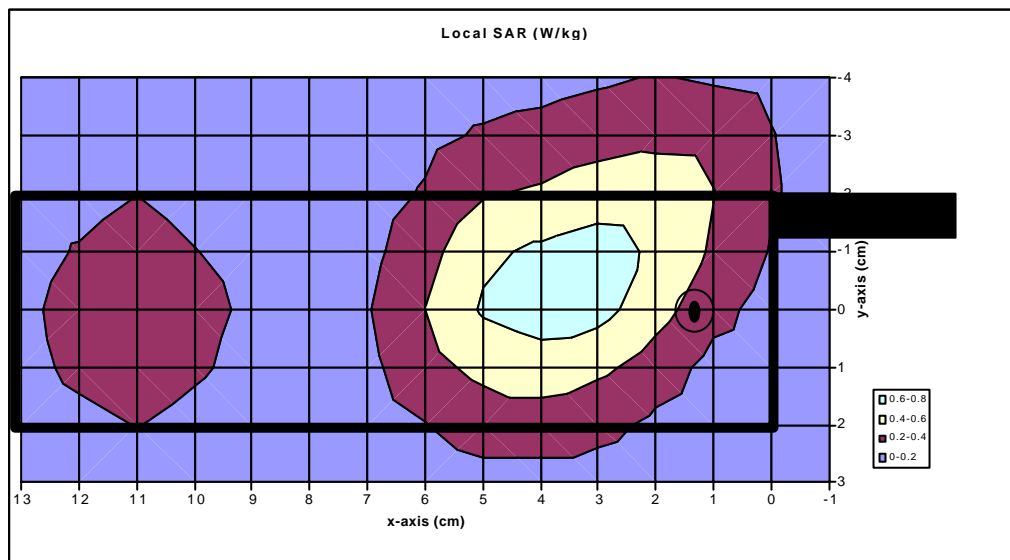

Subsequent testing was performed on the low (991, 824MHz) channel in AMPS mode.

5. The low channel (991, 824 MHz) SAR peak was then explored on a refined 0.5 mm grid in three dimensions. Figures 8, 9, and 10 show the measurements made at 2.5, 7.5, and 12.5 mm respectively. The SAR value averaged over 1 gram was determined from these measurements by averaging the 27 points (3x3x3) comprising a 1 cm cube. The maximum SAR value measured averaged over 1gram was determined from these measurements to be 0.801W/kg.
6. To extrapolate the maximum SAR value averaged over 1 gram to the inner surface of the head phantom a series of measurements were made at a few (x,y) coordinates within the refined grid as a function of depth, with 2.5 mm spacing. Figure 11 in Appendix A shows the data gathered and the exponential curves fit to them. The average exponential coefficient was determined to be  $(-0.0615 \pm 0.0015) / \text{mm}$ .

The distance from the probe tip to the inner surface of the head phantom for the lowest point is 2.5 mm. The distance from the probe tip to the tip of the measuring dipole within the Narda 8021B miniature RF probe is 7 mm. The total extrapolation distance is 9.5 mm, the sum of these two.

7. Applying the exponential coefficient over the 9.5 mm to the maximum SAR value average over 1 gram that was determined previously, we obtain **the maximum SAR value at the surface averaged over 1 gram** of 1.436 W/kg.
  
8. The TDMA phone was also explored on the middle channel (1880MHz) of the 1900 MHz TDMA mode. The SAR value averaged over 1 gram was determined from these measurements by averaging the 27 points (3x3x3) comprising a 1 cm cube. The maximum SAR value measured averaged over 1gram was determined from these measurements to be 0.454W/kg. Then applying the exponential coefficient over the 9.5 mm to the maximum SAR value average over 1 gram that was determined previously, we obtain the maximum SAR value at the surface averaged over 1 gram of 1.241 W/kg for 1900-TDMA (1880MHz). The following diagram shows the overlay at 2.5mm above the phantom's surface.

## 7. CONCLUSIONS

The maximum Specific Absorption Rate (SAR) averaged over 1 gram, determined in the AMPS mode at 824 MHz (channel 991, low) of the Panasonic dual-mode dual-band TDMA phone is 1.436 W/kg. The overall margin of uncertainty for this measurement is  $\pm 14.5\%$ . The SAR limit given in the FCC 96-326 safety guideline is 1.6 W/kg. This unit as tested, is found to be compliant with this requirement.

This unit as tested is found to be compliant with the FCC 96-326 requirement.

### Simulated Tissue Material and Calibration Technique

The mixture used was based on that presented SSI/DRB-TP-D01-033, “Tissue Recipe and Calibration Requirements”.

De-ionised water	40.6 %
Sugar	58.0 %
Salt	1.0 %
HEC	0.3 %
Bactericide	0.1 %

Mass density,  $\rho$  1.30 g/ml  
 (The density used to determine SAR from the measurements was the recommended 1030 kg/m<sup>3</sup> found in Appendix E of Supplement C to OET Bulletin 65, Edition 97-01)

Dielectric parameters of the simulated tissue material were determined using a Hewlett Packard 8510 Network Analyser, a Hewlett Packard 809B Slotted Line Carriage, and an APREL SLP-001 Slotted Line Probe. The dielectric properties are:

Dielectric constant, $\epsilon_r$	42.6
Conductivity, $\sigma$	0.87 S/m
Tissue Conversion Factor, $\gamma$	8.0

## ENGINEERING SUMMARY

This report contains the results of the engineering evaluation performed on a dual-mode dual-band TDMA phone (835 MHz AMPS, 835 MHz TDMA and 1900 MHz TDMA). The measurements were carried out in accordance with FCC 96-326. The dual-mode dual-band TDMA phone was evaluated for its maximum power level in each mode and band.

The phone was tested at high, middle, and low frequencies, for both bands and both modes, with the LCD towards and away from the body with the headset attached. The maximum SAR coincided with the peak performance RF output power of channel 991 (low, 824 MHz), in the AMPS mode. Test data and graphs are presented in this report.

This unit as tested, and as it will be marketed and used (with a warning in the manual to use a case and belt clip that separates the human body by at least 11 mm or 1/2" from the battery), is found to be compliant with the FCC 96-326 requirement, for an uncontrolled RF exposure environment.

## 1. INTRODUCTION

Tests were conducted to determine the Specific Absorption Rate (SAR) of a sample of a Panasonic dual-mode dual-band TDMA phone. These tests were conducted at APREL Laboratories' facility located at 51 Spectrum Way, Nepean, Ontario, Canada. A view of the SAR measurement setup can be seen in Appendix A Figure 1. This report describes the results obtained.

## 2. APPLICABLE DOCUMENTS

The following documents are applicable to the work performed:

- 1) FCC 96-326, Guidelines for Evaluating the Environmental Effects of Radio-Frequency Radiation
- 2) ANSI/IEEE C95.1-1992, IEEE Standard for Safety Levels with Respect to Human Exposure to Radio Frequency Electromagnetic Fields, 3 kHz to 300 GHz.
- 3) ANSI/IEEE 95.3-1992, IEEE Recommended Practice for the Measurement of Potentially Hazardous Electromagnetic Fields – RF and Microwave.
- 4) OET Bulletin 65 (Edition 97-01) Supplement C (Edition 97-01), "Evaluating Compliance with FCC Guidelines for Human Exposure to Radio Frequency Electromagnetic Fields".

## 3. EQUIPMENT UNDER TEST

- Panasonic model EB-TX110A dual-mode dual-band TDMA phone, s/n p6.0 #35
- Panasonic headset
- Panasonic break-out box, revision 3 (used for handset configuration and RF conducted power measurements)
- Magitronic laptop, s/n 015600T08338 (used for handset configuration and RF conducted power measurements)

The antenna is a fixed stub antenna and is located on the left-hand side of the top of the handset. Please refer to Appendix B for photographs of the antenna. The axis of the antenna is 19 mm from the front surface plane of the handset and 19.5 mm from the back surface plane of the handset with a high capacity battery attached.

#### 4. TEST EQUIPMENT

- Narda 8021B miniature E-field probe, s/n 04007, Asset # 301339
- CRS Robotics A255 articulated robot arm, s/n RA2750, Asset # 301355
- CRS Robotics C500 robotic system controller, s/n RC584, Asset # 201354
- HP 438A power meter, s/n 2502A01684, Asset # 301417
- APREL UH-1, Universal Head-Arm, s/n 001, Asset # 301376
- Tissue Recipe and Calibration Requirements, APREL procedure SSI/DRB-TP-D01-033

#### 5. TEST METHODOLOGY

1. The test methodology utilised in the certification of the dual-mode dual-band TDMA phone complies with the requirements of FCC 96-326 and ANSI/IEEE C95.3-1992.
2. The E-field is measured with a small isotropic probe (output voltage proportional to  $E^2$ ).
3. The probe is moved precisely from one point to the next using the robot (10 mm increments for wide area scanning, 5 mm increments for zoom scanning, and 2.5 mm increments for the final depth profile measurements).
4. The probe travels in the homogeneous liquid simulating human tissue. Appendix D contains information about the recipe and properties of the simulated tissue used for these measurements.
5. The liquid is contained in a manikin simulating a portion of the human body.
6. The TDMA phone is positioned in a normal usage position.

7. All tests were performed with the highest power available from the sample dual-mode dual-band TDMA phone, under transmit conditions.

More detailed descriptions of the test method is given in Section 6 when appropriate.

## 6. TEST RESULTS

### 6.1. TRANSMITTER CHARACTERISTICS

The battery-powered transmitter will consume energy from its batteries, which may affect its transmission characteristics. In order to gage this effect the output of the transmitter is sampled before and after each SAR run. In the case of the Panasonic dual-mode dual-band TDMA phone, which has an externally accessible feedpoint, the conductive power was measured. A power meter was connected directly to the device via cable. The following table shows the difference between the sampled power before and after each of the six sets of data used for the worst case SAR in this report. (The device was operating in the AMPS mode in the 835 MHz band, for the worst case SAR.)

Scan		Relative Power Reading (dB)			Battery #
Type	Height (mm)	Before	After	$\Delta$	
Area	2.5	10.80	10.23	-0.57	3
Area	12.5	10.64	10.09	-0.55	1
Zoom	2.5	10.87	10.38	-0.49	1
Zoom	7.5	10.62	10.32	-0.30	3
Zoom	12.5	10.81	10.20	-0.61	1
Depth	2.5 – 17.5	10.66	10.24	-0.42	1

**Note:** the adapter cable loss of 1.6 dB has not been incorporated into these measurements, nor the 13 dB attenuation pad, nor the 0.55dB RF power sensor correction factor (total of 15.15dB).

## 6.2. SAR MEASUREMENTS

- 1) RF exposure is expressed as a Specific Absorption Rate (SAR). SAR is calculated from the E-field, measured in a grid of test points as shown in Appendix A Figure 2. SAR is expressed as RF power per kilogram of mass, averaged in 1 gram of tissue.
- 2) The Panasonic dual-mode dual-band TDMA phone was put into test mode for the SAR measurements via a laptop and break-out box interface (manufacturer supplied) to control the mode, channel and operating power. The phone was initially set to operate in the AMPS mode on channel 991 (low, 824MHz) and its maximum operating power (nominally 375 mW, 25.74dBm).
- 3) Figure 3 in Appendix A shows a contour plot of the SAR measurements for the sample Panasonic dual-mode dual-band TDMA phone operating on the low channel. The presented values were taken 2.5 mm into the simulated tissue from the Universal Head Arm's (UH-a) solid inner surface. Figure 2 in Appendix A shows the UH used in the measurements. The top of the dual-mode dual-band TDMA phone is aligned with the x=zero axis, with the LCD facing down and headset attached. A grid is shown inside of the UH-a indicating the orientation of the x-y grid used, with the co-ordinates (12,-3) at the top left corner. The x-axis is positive towards the left and the y-axis is positive towards the bottom.

A different presentation of the same data is shown in Appendix A Figure 4. This is a surface plot, where the measured SAR values provide the vertical dimension, which is useful as a visualisation aid.

Similar data was obtained 12.5 mm into the simulated tissue. These measurements are presented as a contour plot in Appendix A Figure 5 and surface plot in Figure 6.

Figure 7 in Appendix A shows an overlay of TDMA phone, superimposed onto a contour plot similar to that shown in Figure 3.

Figures 3 through 6 in Appendix A show that there is a dominant peak, in the contour plots, that diminishes in magnitude with depth into the tissue simulation.

- 4) Wide area scans were performed for the low (991, 824 MHz), middle (384, 836 MHz) and high (798, 848 MHz) channels of the AMPS mode respectively, with the LCD facing up and down, and with the headset attached. (The 835 MHz TDMA and 1900MHz TDMA modes were shown to have lower SARs in the associated head SAR report MATB-EBTX110A-3252B). The peak single point SAR for the scans were:

Channel	Channel #	Frequency (MHz)	LCD UP/DOWN	Peak Local SAR (W/Kg)
Low	991	824	UP	1.81
Middle	384	836	UP	1.48
High	798	848	UP	1.78
Low	991	824	DOWN	2.29
Middle	384	836	DOWN	1.88
High	798	848	DOWN	2.16

Subsequent testing was performed on the low (991, 824MHz) channel in AMPS mode, with LCD facing down (battery against the body).

- 5) Wide area scans were also performed for the low (991, 824 MHz) channel versus separation, as well as with the manufacturer supplied case and belt clip. The peak single point SAR for the scans were:

Channel		Antenna's Axis to Phantom's Outer Surface Separation	Highest Local SAR
	(MHz)	(mm)	(W/kg)
Low	824	0	2.29
		5	1.41
		10	1.11
		15	0.75
		fabric case and belt clip	0.45
		25	

Figure 8 in Appendix A shows the data plotted as a function of separation and the exponential curves fit to them.

- 6) The low channel (991, 824 MHz) SAR peak was then explored on a refined 0.5 mm grid in three dimensions at a separation of 10 mm from the UH-a outside bottom. Figures 9, 10, and 11 show the measurements made at 2.5, 7.5, and 12.5 mm respectively. The SAR value averaged over 1 gram was determined from these measurements by averaging the 27 points (3x3x3) comprising a 1 cm cube. The maximum SAR value measured averaged over 1 gram was determined from these measurements to be 0.83 W/kg.
- 7) To extrapolate the maximum SAR value averaged over 1 gram to the inner surface of the head phantom a series of measurements were made at a few (x,y) coordinates within the refined grid as a function of depth, with 2.5 mm spacing. Figure 12 in Appendix A shows the data gathered and the exponential curves fit to them. The average exponential coefficient was determined to be  $(-0.0686 \pm 0.0021) / \text{mm}$ .

The distance from the probe tip to the inner surface of the head phantom for the lowest point is 2.5 mm. The distance from the probe tip to the tip of the measuring dipole within the Narda 8021B miniature RF probe is 7 mm. The total extrapolation distance is 9.5 mm, the sum of these two.

Applying the exponential coefficient over the 9.5 mm to the maximum SAR value average over 1 gram that was determined previously, we obtain **the maximum SAR value at the surface averaged over 1 gram of 1.595 W/kg**.

## 7. ANALYSIS

The measurements of highest peak local SAR versus separation of the axis from the bottom of the phantom (Section 6.2.4) will enable the peak 1gram SAR for a separation of 10mm (previous section) to be extrapolated/interpolated for other separations.

If the data for Figure 8 is fitted to an exponential equation we get:

$$\text{Peak Local SAR} = 1.99 e^{-0.0633 \text{ separation}}$$

A similar equation will exist for the peak 1g SAR versus separation:

$$\text{Peak 1g SAR} = k e^{-0.0633 \text{ separation}}$$

Using this equation with the previous section's data:

Peak 1g SAR = 1.595 W/kg  
separation = 10 mm

results in a  $k = 3.00$  W/kg, which corresponds to the peak 1gram SAR when the separation is zero. A conservative peak 1gram SAR of 1.5 W/kg would occur for a separation of 10.97 mm.

## 8. CONCLUSIONS

The Panasonic dual-mode dual-band TDMA phone used in hands-free mode with the manufacturer supplied case and belt clip will not expose the user to a maximum Specific Absorption Rate (SAR) exceeding the FCC 96-326 SAR safety guideline limit of 1.6W/kg. However, a user not using the manufacturer supplied case and belt clip may be exposed to such levels.

The maximum SAR averaged over 1gram, determined at 824 MHz (low, channel 991), and for a separation between the battery and the phantom of 10 mm, was determined to be 1.595 W/kg. The overall margin of uncertainty for this measurement is  $\pm 14.4$  %. The analysis of the previous section shows that a more conservative 1.5 W/kg will not be exceeded for a separation exceeding 11 mm.

This unit as tested, and as it will be marketed and used (with a warning in the manual to use a case with a belt clip that separates the human body by at least 11 mm, or  $\frac{1}{2}$ " , from the battery), is found to be compliant with the FCC 96-326 requirement.

### Simulated Tissue Material and Calibration Technique

The mixture used was based on that presented SSI/DRB-TP-D01-033, “Tissue Recipe and Calibration Requirements”.

De-ionised water	52.8 %
Sugar	45.3 %
Salt	1.5 %
HEC	0.3 %
Bactericide	0.1 %

Mass density,  $\rho$  1.30 g/ml  
 (The density used to determine SAR from the measurements was the recommended 1040 kg/m<sup>3</sup> found in Appendix E of Supplement C to OET Bulletin 65, Edition 97-01)

Dielectric parameters of the simulated tissue material were determined using a Hewlett Packard 8510 Network Analyser, a Hewlett Packard 809B Slotted Line Carriage, and an APREL SLP-001 Slotted Line Probe. The dielectric properties are:

Dielectric constant, $\epsilon_r$	52.4
Conductivity, $\sigma$	1.08 S/m
Tissue Conversion Factor, $\gamma$	5.1

## 1.0 INTRODUCTION

### 1.1 Purpose and Scope of the Standard

The purpose of this document is to standardize the phantom(s) required for Specific Absorption Rate (SAR) testing associated with SAR measuring systems. This document defines the parts and dimensions of the phantom, in accordance with industry standards and practices.

This Standard defines:

- the methodology and procedures used to define a reproducible representation of the human head, hand and arm
- the dimensions on the canonical shapes used, and the materials required
- the hardware required and the proper setup

This Standard is part of a Certification Program Methodology as described in a separate document entitled "SSI/DBR TP-D01-030, Specific Absorption Rate (SAR) Standard For Portable Telecommunications Devices, March 1998". SSI/DBR TP-D01-031 contains specific criteria that must be met for SAR certification.

### 1.2 Test Facilities

All calibration work as described in this Standard shall be performed at an ISO/IEC Guide 25 accredited laboratory.

### 1.3 Test Personnel

Personnel performing the calibration will be experienced in relevant measurements (e.g. physical properties or RF characteristics) and supervised by a person proficient in SAR measurements.

### 1.4 Standard Environmental Conditions

All measurements and calibration should be performed under normal laboratory conditions for physical properties and electrical characteristics as stipulated by ISO/IEC Guide 25. The nominal temperature for physical property measurements and for electrical characterization are 20°C and 23°C, respectively.

## 2.0 BACKGROUND

Portable communication devices used by consumers typically operate over the range of several watts to a milliwatt, or less, using either analog or digital modulation techniques. Most portable telephones have antennas that radiate within a few centimeters of the user's head. The field strength and field distribution near the antenna are highly dependent on the location, orientation and electromagnetic characteristics of adjacent objects. The head and hand are normally in the reactive near-field region of the antenna where the electromagnetic field is non-propagating. The energy absorbed in the head and hand is mainly due to electric fields induced by the magnetic fields generated by currents flowing through the feedpoint, along the antenna and body of the portable device. The RF energy is scattered and attenuated as it propagates through the tissues of the head, and maximum energy absorption is expected in the more absorptive high water-content tissues near the surface of the head or hand. To account for near-field effects portable devices are evaluated with realistic head models called a phantom.

A phantom is a device that simulates the size, contours, and electrical characteristics of human tissue at normal body temperature. It is composed of a manikin (solid shell) and a tissue-equivalent synthetic material solution (see SSI/DRB-TP-D01-033).

The solid manikin shell is made of a dielectric material, which is transparent to RF energy (i.e. has very low RF absorption), and is as thin as possible while maintaining the strength necessary to hold the mass of simulated tissue.

Current phantoms in use are:

- Universal Head-arm (UniHead) Phantom for ear independent evaluation of the RF exposure in the head of users by telephone-type devices, as well as RF exposure in the head of users of hand held radios positioned in front of the face, and in the hand of users of hand held portable devices
- Flat Phantom for evaluating the RF exposure of other parts of the user body by wireless devices that are not normally used in the vicinity of the head and cannot be accommodated by the UniHead, as well as for experimental investigations. (Such devices would include wireless LAN PCMCIA cards installed in laptop personal computers)
- Insulated Flat Phantom used for the determination of the enhancement factor of synthetic tissue in the calibration of the miniature isotropic electric field (E-field) probes

## 4.0 DEFINITIONS

**manikin:** an RF transparent shell for the phantom

**phantom:** a device that simulates the size, contours, and electrical characteristics of human tissue

## 5.0 PHANTOMS

### 5.1 Universal Head-Arm (UniHead) Phantom

IEC 60959 (TR0 Ed.1.0, 1989, Provisional Head and Torso Simulator for Acoustic Measurements of Air Conduction Hearing Aids) tabulates standard ergonomic data for the human head and torso. A manikin generated from these measurements represents the 95<sup>th</sup> percentile of the population.

#### 5.1.1 Head Simulator

The principle dimensions of the head and torso simulator are shown in Figures 5.1 and 5.2 are listed in Table 5.1.

Table 5.1

A	HEAD BREADTH	152 mm
B	HEAD HEIGHT	141 mm
C	BITRAGION DIAMETER	110 mm
D	NECK DIAMETER	103 mm
E	SHOULDER BREADTH	440 mm
F	CHEST BREADTH	279 mm
G	HEAD LENGTH	199 mm
H	TRAGION TO WALL	97 mm
I	CHIN-VERTEX LENGTH	243 mm
J	TRAGION TO SHOULDER	165 mm
K	SHOULDER DEPTH	116 mm
L	CHEST DEPTH	225 mm
M	SHOULDER POSITION	125 mm

Figure 5.1

Figure 5.2

An engineering approximation for a human head simulator can be made from this ergonomic data using basic canonical shapes. If we define one cylinder with the diameter of the head's breadth (A) and a second with the diameter of the chin's diameter (C) and join the two cylinder with a plane tangent to both cylinders and with a contact separation of  $(I - (A+C)/2)$  we have the basic shape of the head simulator shown in Figure 5.3. This plane defines the "cheek" of the head simulator. The width of the head simulator can be defined by the length of the head (G).

The head simulator is therefore defined by two quarter cylinders, the plane joining these two sections, for an overall length of 243 mm, and limited to a width of 199 mm.

Figure 5.4 shows an alignment aid for positioning a portable communication device. This applique is defined by the positions of the ears and the eyes within the head. By recognizing that both ears are in the center of their respective sides of the head and that the tip of the pinna of the compressed ear coincides with the beginning of the roll-off of the skull cylinder section, we can define a symmetric, ear independent, reference point at (0,0). This is the tip of the composite pinna. Furthermore, the two shaded spots at (0,-7 cm) and (0,+7 cm) correspond to the positions of the humans eyes relative to the ears.

Figure 5.3

Figure 5.4

## 5.1.2 Arm and Hand Simulator

The principal dimensions of the arm and hand are listed in Table 5.2. The hand is represented with a parallelepipedic volume having the dimensions 36x90x110mm. The hand simulator is attached to the head simulator by means of a flexible arm that is attached to a valved nipple. This can provide a continuous conducting link between the liquid in the head where the measurements are taking place and the hand where the handset is being held. Alternatively, with the valve shut, muscle simulating synthetic tissue can be placed in the hand and arm simulator, at the expense of the continuous conducting link.

Table 5.2

	SHOULDER –ELBOW LENGTH	365 mm
	FOREARM-HAND LENGTH	440 mm
	HAND THICKNESS	36 mm
	HAND LENGTH	200 mm
	HAND BREADTH AT THUMB	112 mm
	HAND BREADTH AT METACARPAL	90 mm

Figure 5.5 shows an alignment aid for positioning a portable communication device. This applique is symmetric with respect to the center of the hand simulator. The upper surface of the hand simulator is longer than the defined parallelepipedic volume in order for a dielectric alignment pin to be screwed in to act as a stop for positioning the phone on the hand. In addition, the upper surface is also wider to allow notches to be placed on either side to which an elastic restraint can be attached to hold the portable device in place.

## 5.1.3 Materials

The materials used for the fabrication of the Universal Head–arm (UH-a) are non-metallic. The support platform and base are constructed of laminated wood for easy cleaning (see Figure 5.6 and Table 5.3). The vertical guides are constructed of hard wood giving precision of vertical movement to the measuring gauge and the hand guide. The head- and hand-simulating volumes are made of Plexiglas. The head simulation has the top edge raised above the platform for easy wrapping and removal for storage when containing tissue-simulating liquid. This allows a substitution of phantoms representing different frequencies. Tissue-simulating liquid contained in the hand volume is connected to tissue simulating liquid contained in the head volume by a flexible arm that can be detached for cleaning and storage. The Plexiglas volume of head is formed and terminally stabilized to its exact characteristics. Plexiglas does not include additives for reinforcement. The manufacturing process for the Universal Head–arm allows precise duplication of

## 5.2 Flat Phantom

An acrylic flat phantom with a parallelepipedic volume of 47mm x 14mm x 7mm is used for evaluating the RF exposure of other parts of the user body by wireless devices that are not normally used in the vicinity of the head and cannot be accommodated by the UniHead. (Such devices would include wireless LAN PCMCIA cards installed in laptop personal computers). It can also be suitable for experiment where a larger flat surface is desired that is provided by the UniHead phantom.

### Insulated Flat Phantom

A styrofoam flat phantom with a parallelepipedic volume of 32mm x 21mm x 18 mm is used for the determination of the enhancement factor of synthetic tissue in the calibration of the miniature isotropic electric field (E-field) probes.

## 6.0 SAR LABORATORY SETUP

The phantom is typically setup in relation to the other SAR measurement system equipment as shown in Figure 6.1. The major pieces of equipment for this setup are shown in the Table 6.1.

The articulated robot arm is usually located at one edge or corner of the laboratory space, situated in an RF anechoically damped area. The miniature isotropic E-field probe is attached to the end of the robot arm by means of a dielectric holder which serves the purpose of displacing the probe from the metal of the robot arm that could perturb the RF fields from the portable communication device under test. The phantom is placed in front of the robot arm, on the phantom support fixture, at a distance as far as possible from the robot, but close enough that the E-field probe can explore the entire interior region of the phantom. Again, this is to minimize the perturbations of the RF fields from the portable communication device under test in the vicinity of the robot arm.

The E-field probe is connected to a data acquisition card inside a computer by means of shielded cables. The computer controls the SAR measurement system by controlling the movement of the robot by communicating with its controller, and recording data from the data acquisition card.

## 7.0 TEST CONFIGURATIONS USING THE UNI-HEAD

The Universal Head (Uni-Head) had been originally designed by APREL Laboratories for studies of antenna structures and for optimization of radiating characteristics of handsets. In addition of being a design tool, the Uni-Head may be used for most of measurements required in dosimetry. The figure 7.1 below illustrates some typical scenarios using the Uni-head for various devices under test (DUT).

## 1.0 INTRODUCTION

### 1.1 Purpose and Scope

The purpose of this document is to standardize the test procedures to be followed in calibrating miniature isotropic electric-field (E-Field) probes. This Standard includes the methodology and procedures to be followed in calibrating E-field probes to be used for Specific Absorption Rate (SAR) measurements, in accordance with industry standards and practices.

This Standard defines:

- the methodology and procedures to be followed in the laboratory calibration of the miniature isotropic E-field probes.
- the hardware and software required, the test procedures, and, where applicable, the required limits for calibration of the miniature isotropic E-field probes.

This Standard includes tests to determine the following parameters:

1. Sensor Sensitivity
2. Simulated Tissue Enhancement Factor

This Standard is part of a Certification Program Methodology as described in a separate document entitled "SSI/DBR TP-D01-030, Specific Absorption Rate (SAR) Standard For Portable Telecommunications Devices, March 1998". SSI/DBR TP-D01-032 contains specific criteria that must be met for SAR certification.

### 1.2 Test Facilities

All calibration work as described in this Standard shall be performed at an ISO/IEC Guide 25 accredited laboratory.

### 1.3 Test Personnel

Personnel performing the calibration will be experienced in relevant measurements (e.g. physical properties or RF characteristics) and supervised by a person proficient in SAR measurements.

## 1.4 Test Equipment

The required test equipment, hardware and software, is identified in each individual procedure. Equipment may be substituted or updated from time to time. Should this occur, such change shall be noted in the test report. Equipment shall be calibrated to standards traceable to International Standards.

## 1.5 Standard Environmental Conditions

All measurements and calibration should be performed under normal laboratory conditions for physical properties and electrical characteristics as stipulated by ISO/IEC Guide 25. The nominal temperature for physical property measurements and for electrical characterization are 20°C and 23°C, respectively.

## 2.0 BACKGROUND

The miniature isotropic electric-field (E-field) probe (Fig. 2.1) is a three-channel device used to measure RF electric fields. The sensors are three mutually-orthogonal dipoles, each 2.5 mm, or less, in length. For each channel of the probe, the dipole and two high-impedance lines are deposited on a planar substrate. Located at the center of the dipole is a Schottky diode (shown in Fig. 2.1). The three substrates are assembled to form a beam. Along the substrate are three pairs of high impedance conductors that connect the dipoles to a single output connector. The probe is enclosed in a protective sleeve to avoid contact with the corrosive elements of the simulated tissue. The total length of the probe is approximately 25 cm. The probe does not perturb significantly the field being measured. It is isotropic so that no matter how the probe is positioned relative to the electric field, the sum of the outputs of the three channels always gives the same value. The probe is very fragile, can be damaged by mechanical shock, and should be safely stored when not in use.

In the case of the triangular probe, because of the geometry of the probe elements, if the probe axis is aligned perpendicular to the E-field, and the probe is rotated so that the output of Channel x is maximized, then Channel x's dipole will form a 35.3° angle with the E-field. The relationship between the sensitivity of each channel with the probe axis perpendicular to the electric field ( $\epsilon$ ) to the sensitivity for the E-field tangential to the dipole ( $\eta$ ) is then:

### **3.0 ELECTRIC-FIELD PROBE MEASUREMENT SYSTEM CALIBRATION**

This section describes the tasks necessary to characterize the electrical performance of the E-field probe. Note that two types of calibration are specified. Section 3.1 describes calibration below or at 1 GHz. Section 3.2 describes calibration at frequencies above 1 GHz.

The E-field probe measurement system has two main components: a) the probe, which is connected to the inputs of b) the data acquisition card that is installed in a computer. The probe is connected to the data acquisition card by means of shielded cables. The system is calibrated as one unit, not as individual components. If any component is modified or replaced, the system must be re-calibrated.

The system calibration is performed by determination of the free space E-field from the probe outputs in a test RF field.

### 3.1.2 Definition

The sensitivity of each of the three probe channels is a DC voltage produced at the outputs with the probes exposed to a specified free space electrical field.

### 3.1.3 Minimum Standard

The sensitivity of the probes depends on the manufacturer of the probes and individual components used to manufacture the probes. As such, there is no minimum requirement for sensitivity of the probes.

### 3.1.4 Test Equipment

Description	Manufacturer	Model
RF Signal Generator	Hewlett Packard	8662A
RF Amplifier 0.5 – 1 GHz	APREL	RFPA-1000
TEM Test Cell	Fischer Custom Communications	FCC-TEM-JM1
RF Power Meter	Rohde & Schwarz	NRVS
Miniature E-field probe	Narda	8021B
Probe support fixture	APREL	N/A
Computer	Northern Micro	Pentium 75
Software	Microsoft	Office 97 Pro
Software	APREL	SAR Measurement
Data acquisition card	ComputerBoards	CIO-DAS08-PGH
Miscellaneous Cables	N/A	N/A

### 3.1.5 Test Configuration

Figure 3.1

### 3.1.6 Test Procedure

1. Connect the equipment as shown in the test configuration.
2. Set the RF generator frequency to 1GHz.
3. Adjust the RF generator output so that the power density inside the TEM Cell is 1mW/cm<sup>2</sup>. (For the FCC Model FCC-TEM-JM1 Cell, the correct power level is 153 mW.)
4. Mount the probe of the system to be calibrated in the support fixture.
5. Insert the probe through the side aperture of the TEM Cell. The probe handle should be at the geometric center of the aperture, i.e. midway between the septum and the upper surface, and orthogonal to the side of the Cell. The sensing portion of the probe should be located at a point halfway across the depth of the cell (volumetric center).
6. Once the prescribed position is obtained, it must be maintained during the rest of the measurement. The only movement of the probe allowed is rotation on its axis to position the dipoles in the plane of E-field.
7. Verify that the RF power level remains constant throughout the measurement. While the probe is being rotated through 360 degrees, record the maximum measured on each channel.

Comments and inquiries should be addressed to:

e-mail: inform@spectrum-sciences.org

Ref: Project U404-7-0016 -1997

8. Set the RF generator to a desired calibration frequency and repeat steps 4 through 7.

### 3.1.7 Test Data Table

The sensitivities in mV/ (mW/cm<sup>2</sup>) for each channel can be recorded in the following table:

Frequency	Channel 0 (Pins 6 & 1)		Channel 1 (Pins 2 & 3)		Channel 2 (Pins 4 & 5)	
(MHz)	e	h	e	h	e	h
835						
1000

### 3.2.5 Test Configuration

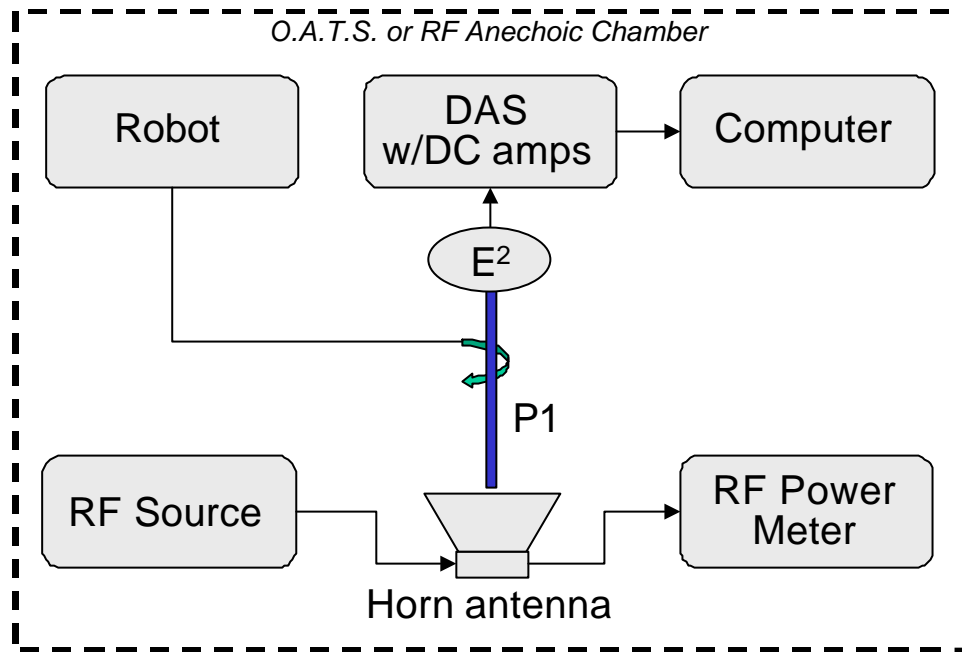

Figure 3.2

### 3.2.6 Test Procedure

1. Mount the miniature RF probe of the system to be calibrated in a support fixture.
2. Setup the equipment so that the horn antenna is coaxial with, and separated from the probe by 1 m.
3. Set the RF generator output at 1GHz.
4. Adjust the RF generator output so that the power density at the miniature RF probe is  $1\text{mW}/\text{cm}^2$
5. Once the prescribed position is obtained, it must be maintained during the rest of the measurement. The only movement of the probe allowed is rotation on its axis to position the dipoles in the plane of E-field.
6. While the probe is being rotated through 360 degrees, record the maximum measured on each channel.
7. Verify the 1 GHz results against those obtained with the TEM cell at the same frequency before proceeding
8. Set the RF generator to a desired calibration frequency and repeat steps 4 through 6.

## 4.6 Test Configuration

Figure 4.1

## 4.7 Test Procedure

1. A RF-transparent thermistor-based temperature probe (used with the Guildline 5150 Precision Dual-Channel Thermometer) and an isotropic E-field probe are placed side-by-side in a planar phantom while both are exposed to RF energy from a half wave dipole antenna located below the phantom (See Fig. 4.1). The E-field probe and data acquisition system was previously calibrated (see Section 3.0).
2. First, the location of the maximum E-field close to the phantom's bottom is determined as a function of power into the dipole.
3. Then, the E-field probe is moved sideways so that the temperature probe, while affixed to the E-field probe, is placed at the previous location of the E-field probe.
4. Finally, temperature changes for 30-second exposures at the same RF power levels used for the E-field measurement are recorded.
5. Care is taken to allow cooling to the original temperature and temperature stabilization between tests. (The heated region of the mixture is briefly stirred to accelerate the process).

- $|E|^2$  is the total RMS E-field level (V/m) induced within the exposed tissue  
 $\sigma$  is the conductivity of the simulated tissue (see SSI/DRB-TP-D01-033)  
 $\rho$  is the density of the simulated tissue (see SSI/DRB-TP-D01-033)  
 $V_i$  are the rectified signal voltages measured on each of the three sensors in the probe  
 $\eta_i$  are the sensor sensitivities relating the signal from a single sensor and the field component in the direction of the sensor  
 $\gamma$  is the tissue enhancement factor which related the sensitivity of the probe in different media to their sensitivity in air.

Taking the derivative of equations (1) and (3) with respect to the RF power (P) delivered to the dipole:

$$\frac{d(SAR)}{dP} = \frac{C}{\Delta t} \frac{d\Delta T}{dP} \quad (4)$$

$$\frac{d(SAR)}{dP} = 3.77 \times 10^{-4} \frac{\mathbf{s}}{\mathbf{r g}} \frac{d}{dP} \left( \sum_1^3 \frac{V_i}{\mathbf{h}_i} \right) \quad (5)$$

Let  $m_T = \frac{d\Delta T}{dP}$  which is the slope of a temperature change ( $\Delta T$ ) versus power (P) graph;

and  $m_V = \frac{d}{dP} \left( \sum_1^3 \frac{V_i}{\mathbf{h}_i} \right)$  which is the slope of the total compensated measured voltage  $\left( \sum_1^3 \frac{V_i}{\mathbf{h}_i} \right)$  versus power (P) graph.

Setting equations 4 and 5 equal to each other and solving for  $\gamma$  we get:

$$\mathbf{g} = 3.77 \times 10^{-4} \frac{\mathbf{s}}{\mathbf{r}} \frac{\Delta t}{C} \frac{m_V}{m_T}$$

## 1.0 INTRODUCTION

### 1.1 Purpose and Scope of the Standard

The purpose of this document is to standardize the recipe for simulated muscle and brain tissue, and the calibration of the simulated tissue. This Standard includes procedures to be followed in making and calibrating simulated biological tissues to be used for Specific Absorption Rate (SAR) measurements.

This Standard defines:

- the methodology and procedures to be followed in the laboratory calibration of the simulated tissues
- the hardware and software required, the test procedures, and, where applicable, the required limits for calibration of simulated tissues.

In addition to recipes for simulated brain and muscle tissues, this Standard also includes tests to determine the following parameters:

1. Density
2. Heat Capacity
3. Dielectric Constant and Conductivity

This Standard is part of a Certification Program Methodology as described in a separate document entitled "SSI/DBR TP-D01-030, Specific Absorption Rate (SAR) Standard For Portable Telecommunications Devices, March 1998". SSI/DBR TP-D01-033 contains specific criteria that must be met for SAR certification.

### 1.2 Test Facilities

All calibration work as described in this Standard shall be performed at an ISO/IEC Guide 25 accredited laboratory.

### 1.3 Test Personnel

Personnel performing the calibration will be experienced in relevant measurements (eg physical properties or RF characteristics) and supervised by a person proficient in SAR measurements.

## 1.4 Test Equipment

The required test equipment, hardware and software, is identified in each individual procedure. Equipment may be substituted or updated from time to time. Should this occur, such change shall be noted in the test report. Equipment shall be calibrated to standards traceable to International Standards.

## 1.5 Standard Environmental Conditions

All measurements and calibration should be performed under normal laboratory conditions for physical properties and electrical characteristics as stipulated by ISO/IEC Guide 25. The nominal temperature for physical property measurements and for electrical characterization are 20°C and 23°C, respectively.

## 2.0 BACKGROUND

In order to perform measurements of specific absorption rates (SAR) of electromagnetic energy in human brain tissue, it is necessary to use models that simulate the electrical properties of real tissue. It is also important that those models are reproducible, long lasting, non-corrosive, and easy to produce and use. Mixtures have been developed that simulate the electrical properties of various biological tissues for various frequency ranges between 100 – 2,450 MHz. This mixture is a practical simulation of biological tissue, however, requires different proportions of sugar, water, salt, hydroxyethylcellulose (HEC) and a bactericide, for different frequency ranges. The solution is easy to produce, and fairly inexpensive. Its electrical properties can be altered to match many tissue types, at different frequencies. For certain frequency ranges, the conductivity of the mixture, even without the presence of salt, will be higher than some of the biological tissues. This will lead to a conservative overestimation of the SAR value. Another advantage of the solution is that its liquid form allows easy positioning of the E-field probe within the phantom. The shelf life of such simulated tissue is reasonably long (weeks) with the addition of the bactericide. Additional precautions (covering, stirring, filtering) may extend the useful life to over six months.

### 4.0 RECIPE AND PREPARATION

#### 4.1 Ingredients

The following table contains recipes for simulated muscle and brain tissues for 100 MHz – 1GHz. This gives approximate quantities required to achieve electrical parameters specified in section in Section 5

Table 4.1

Simulated Tissue Ingredients		
Ingredient	Muscle Mixture	Brain Mixture
Water	52.4 %	40.6 %
Sugar	45.0 %	58.0 %
Salt	1.5 %	1.0 %
HEC	1.0 %	0.3 %
Bactericide	0.1 %	0.1 %

The following table contains recipes for simulated muscle and brain tissues for 1.5 –2.5 GHz. This gives approximate quantities required to achieve electrical parameters specified in section in Section 5

Table 4.2

Simulated Tissue Ingredients	
Ingredient	Brain & Muscle Mixture
Water	45.3 %
Sugar	54.3 %
Salt	0.0 %
HEC	0.3 %
Bactericide	0.1 %

Common household salt and sugar are typically used.

## 4.2 Equipment

The following equipment will be needed to make the simulated tissue.

Table 4.3

Description	Manufacturer	Model
Graduated Cylinder	BOMEX	2000 ml
Storage Container	Various sources	20 l
Weight Scale	Pennsylvania Scale Co.	2 kg
Handling Containers	Various sources	various
Corrosion Resistant Mixing Device		

### 4.3 Preparation

1. Select the appropriate simulated tissue type: Muscle or Brain.
2. From the Tables 4.1 or 4.2 above, determine the percentage of each ingredient for the volume of 20 liters, calculate the mass of each ingredient assuming that the density of the final solution is 1300 kg/m<sup>3</sup>.
3. Verify that the storage container in which the ingredients will be mixed is clean.
4. Obtain the calculated amount of reverse-osmosis or de-ionized water.
5. Pour about 25% of the water into a glass beaker, heat it on a hot plate to almost boiling, and then add it to the cold water. The objective is to increase the temperature of the water to approximately 40° C (100-105°F).
6. Prepare the appropriate quantities of the dry ingredients in separate containers.
7. When the water is ready, slowly add salt and bactericide while stirring at low speed.
8. After the salt and bactericide is dissolved start adding sugar to the container while stirring continuously at low speed until totally dissolved.
9. Add the HEC slowly to avoid clumping. Continue to stir until the solution thickens.
10. Total stirring time should be 30-35 minutes.

## 5.0 MEASUREMENT OF THE DIELECTRIC CONSTANT AND CONDUCTIVITY OF SIMULATED TISSUE

### 5.1 Test Purpose

Before a batch of simulated tissue can be used for SAR measurements, its electrical characteristics (dielectric constant and conductivity) must be determined to ensure that the simulated tissue was properly made and will simulate the desired human characteristics. A coaxial slotted line with probe is used to measure RF amplitude and phase changes versus distance in the simulated tissue as shown below.

### 5.3 Definitions

**dielectric constant:** the ratio of the capacity of a condenser with that substance as dielectric to the to the capacity of the same condenser with a vacuum for dielectric. It is a measure of the amount of electrical charge a given substance can withstand at a given electric field strength.

**conductivity:** the quantity of electricity transferred across unit area, per unit potential gradient, per unit time.

### 5.4 Standard Values Required

The dielectric constant and conductivity of simulated brain tissue should be 46.1 and 0.74 S/m<sup>2</sup>, respectively.

Table 5.1

Tissue Ingredients			
Frequency (MHz)	Tissue Type	Dielectric Constant $\epsilon_r$	Conductivity $\sigma$ (S/m)
835	Brain	41.2	0.90
	Muscle	54.7	1.38
915	Brain		
	Muscle		
1900	Combined	41.0	1.70
2450	Combined

## 5.5 Test Equipment

Table 5.2

Description	Manufacturer	Model
Network Analyzer	Hewlett Packard	8510B
Slotted Line Carriage	Hewlett Packard	809B
Coaxial Termination	Hewlett Packard	908B
Slotted Line Probe	APREL	SLP-001
Miscellaneous Cables and Adapters	N/A	N/A

## 5.6 Test Configuration

Figure 5.1

## 5.7 Test Procedure

1. Before using the slotted line, inspect it carefully to be sure the inside is clean and free of foreign matter.
2. Clean the area about 1 cm wide along each side of the slot. Similarly, clean the underside of the probe outer structure to ensure a good noise-free contact with the slotted line. Take care to avoid damage to the probe center conductor.

Comments and inquiries should be addressed to:

RF Dosimetry Research Board (DRB)  
Spectrum Sciences Institute  
51 Spectrum Way, Nepean, Ontario, Canada K2R 1E6  
Tel. (613) 820-6471 Fax (613) 820-4161  
e-mail: [inform@spectrum-sciences.org](mailto:inform@spectrum-sciences.org)

Ref: Project U404-7-0016 -1997

3. Using a large syringe, draw up a sample of room temperature simulated tissue. Ensure that the sample is as free as possible of air bubbles, and inject the simulated tissue into the slot. Make sure that the slot is full of simulated tissue and free of air bubbles.
4. Connect Port 1 of the network analyzer to the probe, and Port 2 to the slotted line.
5. Insert the slotted line probe into the probe holder and tighten the thumbscrew.
6. Move the holder to the end nearest the input connector, making sure that the simulated tissue is flush with the outside surface of the line. Align one end of the probe marker with a line on the centimeter scale.
7. Set the network analyzer's frequency range to cover the measurement frequencies and select the  $S_{12}$  parameter.
8. Select port-to-port loss measurement and select averaging over a sufficient number of samples.
9. After averaging, place the marker at a frequency of interest and record the level in the table (one table per frequency) to the nearest 0.1dB.
10. Select phase measurement (averaging should be left on). Place the marker at a frequency of interest and record in the phase in the table (one per frequency) to the nearest  $0.1^\circ$ .
11. Move the probe 0.5cm toward the far end of the line.
12. Repeat steps 7 through 11 until 13 data points (corresponding to 6 cm) have been measured.

## 5.8 Test Data Table

1. The level and phase can be recorded in the following table (use one copy per frequency):

Table 5.3

Frequency:	Date:	
Position (cm)	Level (dB)	Phase (°)
0.0		
0.5		
1.0

2. Execute the Fluid Calibration with Slotted Line.xls spreadsheet and enter the measured amplitude and phase data as recorded in the table(s). When the data are plotted (eg Figure 5.2), examine the linearity of the curves to judge the validity of the calculated dielectric constant and conductivity (eg Table 5.4). If only one point on a curve is out of line, re-measure just that point. If more than one point is wrong, repeat the entire measurement. Once the data are satisfactory, the calculated values should be compared with the values in Table 5.1.
3. The measured data, calculated values, and plot must be identified with the type of simulated tissue, date it was prepared, frequency, date and name of person conducting the measurements, and kept in a file.
4. The simulated tissue should be used soon after preparation and characterization of the dielectric properties, and stored so as to prevent evaporation of the water. After prolonged use, a sample should be taken for dielectric measurement to assure there has been no change in properties. In the absence of biological degradation and significant evaporation, the simulated tissue can be used for several months.

## 5.9 Test Data Analysis

The data from the slotted line are used to determine the relative dielectric constant and effective conductivity (that includes contributions from both dielectric and ohmic processes) from the following relationships:

$$\epsilon_r = \frac{b^2 - a^2}{w^2 \mu \epsilon_0} \quad (1)$$

$$s_{\text{effective}} = \frac{2ab}{wm} \quad (2)$$

$\alpha$  and  $\beta$  are determined by averaging, respectively, the attenuation (dB/cm) and phase shift (deg/cm) over the length of the slotted line. The attenuation and phase shift are each determined for seven pairs of points. Each of the pairs of points is from measurements separated by 3 cm. For example (using the data in Table 5.4), the attenuations and phase shifts at  $z=1$  cm and  $z=6$  cm define  $\Delta\text{dB}_1$  and  $\Delta\text{deg}_1$ :

$$\begin{aligned} \Delta\text{dB}_1 &= \text{Mag}(z = 3 \text{ cm}) - \text{Mag}(z = 0 \text{ cm}) \\ &= -45.9 \text{ dB}_m - (-37.9 \text{ dB}_m) = -8.0 \text{ dB, and} \end{aligned}$$

$$\begin{aligned} \Delta\text{deg}_1 &= \text{Phase}(z = 3 \text{ cm}) - \text{Phase}(z = 0 \text{ cm}) \\ &= 83.8 \text{ deg} - (285.6) \text{ deg} = -201.8 \text{ deg.} \end{aligned}$$

In a similar fashion, obtain data for  $\Delta\text{dB}_2$  to  $\Delta\text{dB}_6$  and  $\Delta\text{deg}_2$  to  $\Delta\text{deg}_6$  and then average each series to get

$$\begin{aligned} \mathbf{a}_{\text{avg}} \text{ (dB/cm)} &= \frac{\sum_{n=1}^7 \Delta\text{dB}_n}{7 \cdot 3}, \text{ and} \\ \mathbf{b}_{\text{avg}} \text{ (deg/cm)} &= \frac{\sum_{n=1}^7 \Delta\text{deg}_n}{7 \cdot 3} \end{aligned}$$

The values of  $\alpha_{\text{avg}}$  and  $\beta_{\text{avg}}$  must be converted to units of (Np/cm) and (rad/cm) using these relations:

$$\hat{\alpha}_{\text{avg}} \text{ (Np/cm)} = \frac{\ln(10) \cdot \hat{\alpha}_{\text{avg}} \text{ (dB/cm)}}{20}, \text{ and}$$

$$\hat{\alpha}_{\text{avg}} \text{ (rad/cm)} = \frac{\hat{\alpha}_{\text{avg}} \text{ (deg/cm)} \cdot \delta}{20}$$

Finally, use (1) and (2) to obtain  $\epsilon_r$  and  $\sigma_{\text{effective}}$  from  $\alpha_{\text{avg}}$ ,  $\beta_{\text{avg}}$ , and  $\omega = 2\pi f$ , where  $f$  is the frequency of the RF field.

## 6.0 MEASUREMENT OF THE SPECIFIC HEAT CAPACITY OF SIMULATED TISSUE

### 6.1 Test Purpose

The specific heat capacity of the synthetic tissue liquid is required in the calibration of the miniaturized isotropic E-field probes used to measure the Specific Absorption Rate (SAR). A sample of the liquid is exposed to the known field of an RF radiation for a specific length of time. The liquid will be heated and this heat can be propagated by conduction, convection, and radiation. In the case of liquids heated from below, gravity convection is the main and predominant heating mechanism of the fluid mass.

### 6.3 Definition

**specific heat capacity:** the quantity of energy needed to raise the temperature of a unit mass by one degree.

## 6.4 Standard Value

For brain tissue simulating liquids the heat capacity should be 2.8 J/K/g  $\pm$ 5%.

## 6.5 Test Equipment

Table 6.1

Description	Manufacturer	Model
Differential Thermometer		
Containers (2)		500 ml
Thermally Insulated Vessel		
Weigh Scale	Pennsylvania Scale Co.	2 kg
Graduated Cylinder	BOMEX	2000 ml
Data Recorder		

## 6.6 Test Procedure

1. Obtain two containers that can be rapidly heated (e.g., glass or suitable plastic).
2. Fill one container with 250 ml of water; the other with the same mass of simulated tissue. The initial temperature of the water should be the same as that of the simulated tissue ( $\pm 1^\circ\text{C}$ ). Since we are dealing with heating by electromagnetic sources at ambient temperature, it is essential that we eliminate the chance of any direct infrared heating of the temperature sensor.
3. To ensure this, position the tip of the sensor 2mm from the bottom of the center of the container.
4. Turn on the heat source and wait at least 5 minutes for its temperature to stabilize.
5. Record the initial temperature of the water.
6. Place the container of water 5mm above the center of the hot plate and monitor the temperature increase.
7. After 30 seconds of heating, the water temperature should have increased by at least  $5^\circ\text{C}$ . Record the time and temperature.
8. Remove the container from the heat source and place it in the thermally insulated vessel.

9. Stir the liquid thoroughly and record the steady-state temperature 1-2 minutes after stirring.
10. Repeat the above procedure using the container of simulated tissue. Ensure that the container is placed on the same area of the hot plate, is heated for the identical length of time, and the steady-state temperature is recorded after the identical time interval.

## 6.7 Test Data Table

The temperatures can be recorded below.

Table 6.2

Trial	Water (°C)			Tissue (°C)		
	Initial Temp	30 seconds	120 seconds	Initial Temp	30 seconds	120 seconds
1						
2						
3						
4						
5						
6						
7						
8						
9						
10						

## 6.8 Test Data Analysis

Since the heat capacity of water is  $C_w = 1 \text{ cal/}^\circ\text{C/g}$  with excellent approximation ( $\sim 1\%$ ) in the temperature range of interest, the heat capacity ( $C_s$ ) of the solution is given by

$$C_s = C_w \frac{\Delta T_w}{\Delta T_s}$$

where  $\Delta T_w$  is the temperature increase of water and  $\Delta T_s$  the temperature increase of the solution. The ratio of the values,  $\Delta T_w/\Delta T_s$ , should be the same (within the sensitivity of

the thermometer) at the end of the heating and stirring. This ensures that the liquids have been uniformly heated.

## 6.9 Rationale

$C \Delta T = \text{Heat flow} \times \text{time} = \text{Total Heating Energy}$

If the heat flow, sample mass, and absorption (heat transfer) are the same for both liquids, then

$$C_W \Delta T_W = C_S \Delta T_S$$

The heat flow and total heating are kept constant by using the same source for the same amount of time. If the heat transfer mechanisms for the two liquids are about the same, with insignificant differences in convective and conductive characteristics, then any differences in temperature increase are a direct measure of the specific heat capacity,  $C$ .

## 7.0 MEASUREMENT OF THE DENSITY OF SIMULATED TISSUE

### 7.1 Test Purpose

Before a batch of simulated tissue can be used for SAR measurements, its density must be determined to ensure that the simulated tissue was properly made and will simulate the desired human characteristics.

### 7.2 References

- Introduction to Physics for Scientists and Engineers, F.J. Bueche, 1980, McGraw-Hill Book Company, New York.
- “Electromagnetic Energy Exposure of Simulated Users of Portable Cellular Telephones”, Q. Balzano, O.M. Garay, and T.J. Manning, 1995, IEEE Transactions on Vehicular Technology, 44:390-403.
- “Broadband Calibration of E-Field Probes in Lossy Media”, K. Meier, M. Burkhardt, T. Schmid, and N. Kuster, 1996, IEEE Transactions on Microwave Theory and Techniques, 44:1954-1962.

### 7.3 Definition

**density:** a measure of the mass contained in a unit volume of the substance.

### 7.4 Standard Value

For brain tissue simulating liquids the density should be  $1.28 \text{ g/cm}^3 \pm 2\%$ .

### 7.5 Test Equipment

Description	Manufacturer	Model
Weigh Scale	Pennsylvania Scale Co.	2 kg
Graduated Cylinder	BOMEX	2000 ml

## 7.6 Test Procedure

1. Obtain a clean, dry graduated cylinder.
2. Place the cylinder on a scale and record its mass when empty.
3. Pour a sample of the simulated tissue into the cylinder.
4. Weigh the cylinder with the simulated tissue to obtain a total mass.
5. Subtract the cylinder mass from the total mass to obtain the mass of the tissue.
6. Record the tissue volume and mass in the table below.
7. Clean and dry the cylinder and repeat this process for a total of 10 trials.

## 7.7 Test Data Table

- 1 The volume and mass can be recorded in the following table:

<b>Mixture Frequency (MHz):</b>		<b>Date:</b>	
<b>Empty Measuring Container Mass (g):</b>			
<b>Trial</b>	<b>Volume (ml)</b>	<b>Mass (g)</b>	<b>Density (g/ml)</b>
1			
2			
3			
4			
5			
6			
7			
8			
9			
10			

## 7.8 Test Data Analysis

The data are used to determine the density of the simulated tissue by means of the following relation:

$$r = \frac{m - m_c}{v}$$

where  $\rho$  is the density ( $\text{g}/\text{cm}^3$ , Note:  $1 \text{ g}/\text{cm}^3 = 1000 \text{ kg}/\text{m}^3$ )  
 $m$  is the mass of the container filled with simulated tissue (g)  
 $m_c$  is the mass of the empty container (g)  
 $v$  is the volume of the simulated tissue ( $1 \text{ cm}^3 \equiv 1 \text{ ml}$ ).

## **1.0 INTRODUCTION**

### **1.1 Purpose and Scope of the Standard**

The purpose of this document is to standardize the portable transmitter positioning and E-field scanning inside the phantom that simulates parts of the human body for Specific Absorption Rate (SAR) measurements.

This Standard defines:

- the methodology and procedures to be followed in the laboratory to setup the portable handset
- the procedure to define the E-field area scanning
- the procedure to determine zoom scan to derive the 1 or 10 gram average SAR.

This Standard is part of a Certification Program Methodology as described in a separate document entitled "SSI/DBR TP-D01-030, Specific Absorption Rate (SAR) Standard For Portable Telecommunications Devices, March 1998". SSI/DBR TP-D01-034 contains specific criteria that must be met for SAR certification.

### **1.2 Test Facilities**

All calibration work as described in this Standard shall be performed at an ISO/IEC Guide 25 accredited laboratory.

### **1.3 Test Personnel**

Personnel performing the calibration will be experienced in relevant measurements (eg physical properties or RF characteristics) and supervised by a person proficient in SAR measurements.

### **1.4 Test Equipment**

The required test equipment, hardware and software, is identified in each individual procedure. Equipment may be substituted or updated from time to time. Should this

occur, such change shall be noted in the test report. Equipment shall be calibrated to standards traceable to International Standards.

## 1.5 Standard Environmental Conditions

All measurements and calibration should be performed under normal laboratory conditions for physical properties and electrical characteristics as stipulated by ISO/IEC Guide 25. The nominal temperature for physical property measurements and for electrical characterization are 20°C and 23°C, respectively.

## 2.0 BACKGROUND

### 2.1 Positioning of the Device Under Test (DUT)

In positioning a portable communication device with respect to the simulated human body, we are interested in obtaining the worst coupling between the device and the head while ensuring that such a position is a reasonable approximation of a common usage position.

SAR inside the head is predominantly attributable to the H-fields produced by the currents inside the handset or along its antenna. These H-fields cause currents in the boundary of the phantom, which in turn induce E-fields within the simulated tissue. These E-fields give rise to the measured SAR within the portion of the simulated human body being exposed.

The exact sources of the highest H-fields within the phone are not usually known. However, the antenna feedpoint area is normally the prime suspect. The coupling of a high current producing area with the simulated tissue causes deposition of energy into the simulated tissue as well as modifications to characteristics of the transmitting source itself.

If a large plastic case, with various internal components, is coupled to simulated tissue, and the coupled area does not carry current, or the current carrying area is remote (in relative terms), there will be no significant SAR deposited in the tissue, nor will there be any significant change of the source.

The purpose of various standards (e.g. CENELEC), or industry practices, is to position the handset with respect to an arbitrary shape of the head in such a way that the coupling between the tissue and the current source is the strongest.

The Universal Head-arm (UniHead) is engineered in such a way that the maximum coupling can be found without maneuvering the handset through various positions. This is

achieved by placing the handset at a constant position and a constant displacement relative to the phantom. Thus the SAR generating area, wherever it is in the handset, will always couple to the simulated tissue. This makes maneuvering of the handset (3 angles, left-right ear, 3 point contact, etc.) redundant.

The commonly accepted distance between the tissue boundary and the handset is 6 mm (2 mm shell + 4 mm for the compressed human ear).

In the practice of measuring SAR a plastic layer forms part of the space between the tissue boundary and the phone. The dielectric and conductive characteristics of this layer of plastic are relatively close to those of air in comparison to those of the simulated tissue. It is believed in today's practice that this layer does not have any other role than creating a distance between the device surface and the tissue boundary. However, an investigation of the measuring uncertainty produced by the presence of plastic are not very complete. In the UniHead, for the sake of precision and repeatability, the only layer which is introduced is the one that is needed to contain the tissue simulation and no additional arbitrarily shaped space is introduced.

In the research carried out by APREL Laboratories for Spectrum Sciences Institute, much of which was witnessed by industry, it was demonstrated that when the current was flowing in the parts of the phone closer to the head than the hand simulation, there was essentially no impact on the SAR distribution or the peak SAR value (< 10% difference). However, in instances when the current carrying components are closer to the hand than to the head, the impact on the handset performance and peak SAR value is significant, and should not be neglected.

In the instances where there is a requirement for measurement without the hand, the Universal Head is engineered in such a way that the simulated tissue can be easily removed from the hand simulation and thus becomes a positioning bracket with marginal quantities of plastic with a marginal impact on the radiated fields.

## 2.2 Area Scanning

A head model is usually placed on its side, which allows a handset to be placed underneath the head to facilitate field measurements. The field probe is inserted into the liquid from above and measurements can then be made on the inside surface of the head next to the phone. SAR measurements usually start with a coarse measurement at 1-2 cm resolution where the electric field probe is scanned throughout the entire region of tissues next to the handset and its antenna. This provides a SAR distribution near the surface of the phantom, closest to the phone, where the approximate location of the peak SAR can be identified.

### 2.3 Zoom Scanning and 1g or 10g Averaging

A smaller region centered on the peak SAR location is then scanned with a 1-5 mm finer resolution to determine the one-gram average SAR. The measurements obtained from this fine resolution scan are averaged over a 1-cm<sup>3</sup> volume in the shape of a cube to determine the one-gram average SAR. A 10-cm<sup>3</sup> volume for a ten-gram average SAR is appropriate for the extremities in North America, or for all requirements in Europe or Japan. The average density of most high water-content tissues is about 1020-1040 kg/m<sup>3</sup>, which requires the tissue volume to be about 1 cm long on each side. For a 10-gram average SAR a tissue volume of 2 cm long on each side can be used produce a conservative overestimate of the SAR value (the actual side length should be 2.125 cm). The number of measurement points required in the fine scan to provide accurate one-gram average SAR is dependent on the field gradients at the peak SAR location. In smooth gradients, the one-gram average SAR can be correctly predicted with only a few measurement points. When steep field gradients exist, many measurement points evenly distributed within a cubic centimeter of the tissue material may be required to correctly predict the one-gram average SAR. To overcome this problem, a curve-fitting process may be applied to the measured data to allow more points to be used in the average.

The measurements provided by electric field probe normally do not correspond to the location at the tip of a probe because the detectors are located behind the tip. For homogeneous phantoms, the peak field values are at the surface of the phantom, but the detectors of the probe are generally 2.5-7.0 mm behind the tip of the probe. Therefore the field measurements must be extrapolated to the surface of the phantom to compensate for field attenuation introduced by this offset distance. This can be done by taking a number of measurement points in a straight line perpendicular to the phantom surface at the peak SAR location and applying a curve-fitting process for the extrapolation.

If measurements in the immediate vicinity of the phantom surface are included in the extrapolation routine, the boundary effect of the probe must be considered. The boundary effect results in an increased sensitivity of the probe and is caused by the interaction of the field disturbance around the probe with the boundary. The strength of the overestimation depends on the probe dimensions, the probe distance from the surface, the boundary curvature, the probe angle to the surface and the field decay in the solution. If the boundary effect is not completely compensated for in the software, a positive error offset (overestimation) of the spatial peak SAR will occur. An alternative approach is to dismiss all measurements near the surface and extrapolate over a longer distance. This will eliminate the offset error, but largely increase the error due to extrapolation uncertainty.

The actually assessed cube is a surface adapted "cube" as opposed to a geometrical cube. This is partially due to the missing definition of the cube placement and partially due to the mechanics of the data acquisition systems which operate in a Cartesian coordinate system.

## 4.0 DEVICE UNDER TEST (DUT) POSITIONING PROCEDURES

### 4.1 DUTs Held Against the Ear

1. Select the simulated tissue appropriate for the type of tissue being tested, and the operating frequency of the DUT, and fill the Universal Head-arm (UniHead) with it.
2. Allow sufficient time for all air bubbles to escape before performing a scan.
3. Lift up the measurement slide (see Figure 4.1) and place the DUT face-up under it. Lower the measurement slide so that it rests on the DUT and record the height on the scale to the left of the slide using the lower edge of the slide as reference.
4. Add 4 mm to this height to account for the spacing provided by a compressed human ear and record the value.

Figure 4.1

5. Put the DUT into test mode at the highest rated power, and operating on either the maximum performance frequency or one of the low, middle and high channels.
6. Loosen the bolt (on the right side of the UniHead stand) holding the hand simulator support, using the orange finger tab, and lower whole structure. Pull out the sliding support, using its orange finger tab (Figure 4.2), so that the DUT simulator is easily accessible.
7. Position the DUT on top of the hand simulator, butting the top of it up against the reference pin, and centered within the locating lines (see Figure 4.3).

8. Use a rubber band (elastic) to hold the DUT in place making use of the two notches on either side of the hand simulator (see Figure 4.2).

Figure 4.2

9. Slide the hand simulator back under the UniHead until it stops against the mechanical stop. This will locate the device properly in a horizontal plane in relation to the head simulator.
10. Slide the hand simulator support up until the top or the support lines up with the height determined in step 4 above.
11. Looking from above the device should be lined up as shown in Figure 4.4

Figure 4.3

Figure 4.4

## 4.2 DUTs Held In Front of the Mouth (e.g. PPT radio like handset)

1. Perform steps 1 through 9 as in Section 4.1.
2. Lower the device by 30 mm to account for the spacing provided by a human nose.
3. Looking from above the device should be lined up as shown in Figure 4.4

## 4.3 DUTs Used in the Hand Away from the Body (e.g. point of sale device)

The head simulator can be used as a substitute for the hand when performing a SAR evaluation for a device that is normally held in the hand but is not used in the vicinity of the head or the body. In this case the hand simulator should be empty (i.e. it will not contain simulated tissue) and will act strictly as a support to hold the DUT. The hand substitute (i.e. the head simulator) should be filled with simulated muscle tissue.

1. Close the valve between the head simulator and the hand simulator. This will ensure that the hand simulator remains empty and will serve only as a support for the DUT (if the hand is full of simulated tissue from a previous procedure, disconnect and empty it).
2. Select the simulated tissue appropriate for the type of tissue being tested, and the operating frequency of the DUT, and fill the head simulator portion of the UniHead with it.
3. Allow sufficient time for all air bubbles to escape before performing a scan.
4. Lift up the measurement slide (see Figure 4.1) and place the DUT face-up under it. Lower the measurement slide so that it rests on the DUT and record the height on the scale to the left of the slide using the lower edge of the slide as reference.
5. Add 30 mm to this height to account for the spacing provided by a human nose and record the value.
6. Put the DUT into test mode at the highest rated power, and operating on either the maximum performance frequency or one of the low, middle and high channels.
7. Loosen the bolt (on the right side of the UniHead stand) holding the hand simulator support, using the orange finger tab, and lower whole structure. Pull out the sliding support, using its orange finger tab (Figure 4.2), so that the DUT simulator is easily accessible.
8. Position the DUT upside-down on top of the hand simulator, butting the top of it up against the reference pin, and centered within the locating lines (see Figure 4.3).
9. Use a rubber band (elastic) to hold the DUT in place making use of the two notches on either side of the hand simulator (see Figure 4.2).
10. Slide the hand simulator back under the UniHead until it stops against the mechanical stop. This will locate the device properly in a horizontal plane in relation to the head simulator.

11. Slide the hand simulator support up until the top or the support lines up with the height determined in step 5 above.
12. Looking from above the device should be lined up as shown in Figure 4.4

#### 4.4 DUTs Carried Next to the Body

The head simulator can be used as a substitute for the body, or thighs, when performing a SAR evaluation for a device that is normally positioned against the body. These devices include backpack, shoulder strap or belt mounted portable communication gear as well as those installed into laptop computers. In this case the hand simulator should be empty (i.e. it will not contain simulated tissue) and will act strictly as a support to hold the DUT. The body or thigh substitute (i.e. the head simulator) should be filled with simulated muscle tissue.

- 1 Close the valve between the head simulator and the hand simulator. This will ensure that the hand simulator remains empty and will serve only as a support for the DUT (if the hand is full of simulated tissue from a previous procedure, disconnect and empty it).
- 2 Select the simulated tissue appropriate for the type of tissue being tested, and the operating frequency of the DUT, and fill the head simulator portion of the UniHead with it.
- 3 Allow sufficient time for all air bubbles to escape before performing a scan.
- 4 Lift up the measurement slide (see Figure 4.1) and place the DUT face-up under it. Lower the measurement slide so that it rests on the DUT and record the height on the scale to the left of the slide using the lower edge of the slide as reference.
- 5 Add 30 mm to this height to account for the spacing provided by a human nose and record the value.
- 6 Put the DUT into test mode at the highest rated power, and operating on either the maximum performance frequency or one of the low, middle and high channels.
- 7 Loosen the bolt (on the right side of the UniHead stand) holding the hand simulator support, using the orange finger tab, and lower whole structure. Pull out the sliding support, using its orange finger tab (Figure 4.2), so that the DUT simulator is easily accessible.
- 8 Position the DUT upside-down on top of the hand simulator, butting the top of it up against the reference pin, and centered within the locating lines (see Figure 4.3).
- 9 Use a rubber band (elastic) to hold the DUT in place making use of the two notches on either side of the hand simulator (see Figure 4.2).
- 10 Slide the hand simulator back under the UniHead until it stops against the mechanical stop. This will locate the device properly in a horizontal plane in relation to the head simulator.

- 11 Slide the hand simulator support up until the top or the support lines up with the height determined in step 5 above.
- 12 Looking from above the device should be lined up as shown in Figure 4.4

## 5.0 AREA SCANNING PROCEDURE

Once the DUT is properly positioned with respect to the UniHead, a coarse scan of the electric field generated by the DUT can be made using a miniature isotropic E-field probe, throughout the entire region of tissues next to the handset and its antenna. This provides a SAR distribution near the surface of the phantom, closest to the phone, where the approximate location of the peak SAR can be identified.

### 5.1 Definition

**area scan:** measurement of the electric field inside the simulated tissue, over an array of positions following the inside surface of the phantom, and covering the entire region. The resolution of the scan is usually 1-3 cm.

## 5.2 Test Equipment

Table 5.1

Description	Manufacturer	Model
Articulated Robot Arm	CRS Robotics	A255
Robotic System Controller	CRS Robotics	C500
Phantom	APREL	UniHead
Phantom support fixture	APREL	various
Synthetic Tissue Mixture	APREL	SSI/DRB-TP-D01-033
Miniature E-field probe	Narda	8021B
Probe support fixture	APREL	N/A
Computer	Northern Micro	Pentium 75
Software	CRS Robotics	RobComm
Software	Microsoft	Office 97 Pro
Software	APREL	SAR Measurement
Data acquisition card	ComputerBoards	CIO-DAS08-PGH
Miscellaneous Cables	N/A	N/A

## 5.3 Test Procedure

1. Ensure that the UniHead is level.
2. Start RobComm, open FLATSAR.TXT, and start Dashboard. Use the mouse to push RESET button and then the GO button. This will place the miniature E-field probe above the UniHead in its start position.
3. Close Dashboard and put RobComm in Terminal mode.
4. Type STATUS and check that the tool transform in effect is REF25.
5. Move the probe to (x,y) coordinates (12,8) on the grid (see Figure 5.1).
6. Adjust the probe height so that it is 2.5 mm above the phantom surface.
7. Set the position BEGIN to this probe location.
8. Move the probe 12 cm along the x-axis. If the probe does not follow the grid line, move the probe back 12 cm, and then readjust the UniHeads position and try again by moving the probe 16 cm along the y-axis. If the probe still does not follow a

grid line, move the probe back 16 cm along the y-axis, and readjust the UniHead position again.

Figure 5.1

9. Repeat step 7 until the robot's x- and y-axes coincide with the UniHead's.
10. Exit Terminal Mode and restart Dashboard. Use the mouse to push RESET button and then the GO button. This will place the miniature E-field probe above the UniHead in its start position.
11. From the Application Menu select FLATSAR.XLS. Microsoft Excel will open this file automatically.
12. Enter a name for the spreadsheet that will be created with the measurement data. The file name should include the DUT model number, measurement height, "area" and date.
13. Select the scan resolution of 10 mm. The default scan resolutions available are 10 mm and 5 mm. The default x and y spans are 16 cm and 8 cm, for 10 and 5 mm resolutions, respectively. (The x-axis is along the DUT and y-axis is across the DUT). If other scan resolutions or spans are desired, then the Visual Basic code will have to be edited.
14. Start the scan by pushing the ACQUIRE DATA button with the mouse pointer. The application will now run automatically and acquire the data.

15. Once the application has stopped, quit the application. Reenter Terminal mode and change the tool transform to REF125. Type STATUS and verify that the tool transform in effect is REF125.
16. Repeat steps 10-14. This creates a spreadsheet with a second scan data set 1 cm further away from the surface of the phantom.
17. Once the application has stopped, quit the application. Print out the surface and contour plots for each of the 2 spreadsheets.

## **6.0 ZOOM SCANNING AND 1 OR 10 GRAM AVERAGING PROCEDURES**

A smaller region centered on the peak SAR location identified with the area scan is then scanned with a 5 mm finer resolution to determine the one-gram, or ten-gram, average SAR. The measurements obtained from this fine resolution scan are averaged over a 1-cm<sup>3</sup> volume in the shape of a cube to determine the one-gram average SAR, or an 8-cm<sup>3</sup> volume for a ten-gram average SAR.

The spatial peak SAR is calculated from a large number of values (27); measured in a volume of 80 x 80 x 10 mm around the maximum local SAR (867 values in total). A numerical procedure then searches for the 1-cm<sup>3</sup> or 8-cm<sup>3</sup> cube with the highest average SAR within this data array.

An exponential extrapolation to the surface is then applied based on measurements made on 4 or 5 grid locations, at 2.5 mm intervals between 2.5 and 17.5 mm from the inside surface of the phantom.

An exponential extrapolated to the surface of the phantom is then applied to compensate for the field attenuation introduced by the 7 mm offset distance between the E-field detectors to the tip of the probe and the 2.5 mm distance from the lowest measurements to the surface. The extrapolation is calculated from 5 sets of data taken in a straight line perpendicular to the phantom surface at the peak SAR location and applying an exponential curve-fitting routine for the extrapolation. The location of these sets is at the center of the peak SAR cube and the 4 next nearest (x,y) coordinates.

## 6.1 Definitions

**zoom scan:** measurement of the electric field inside the simulated tissue, over an array of positions following the inside surface of the phantom, and covering a region in the vicinity of the peak(s) identified with an area scan. The resolution of the scan is usually 1-5 mm.

**1-g average:** the peak energy absorption rate averaged over the 1 g of tissue in the shape of a cube. Since the average density of simulated muscle or brain tissue is 1020-1040 kg/m<sup>3</sup> this ideally corresponds to a side length of 0.987 – 0.993 cm. In practice, 1 cm sides are normally used.

**10-g average:** the peak energy absorption rate averaged over the 10 g of tissue in the shape of a cube. Since the average density of simulated muscle or brain tissue is 1020-1040 kg/m<sup>3</sup> this ideally corresponds to a side length of 2.126 - 2.140 cm. In practice, 2 cm sides are normally used.

## 6.2 Zoom Scanning Procedure

1. Review the plots obtained from the area scan and determine one set of grid coordinates ( $x_m$ ,  $y_m$ ) that is closest to the maximum SAR value measured on each of the two sets of area scans. The maximums on the two levels are usually at the same coordinates, or with a cm or so of each other.
2. Close Dashboard, put RobComm in Terminal mode and change the tool transform to REF25. Type STATUS and verify that the tool transform in effect is REF25.
3. Move the probe to (x,y) coordinates ( $x_m+4\text{cm}$ ,  $y_m+4\text{cm}$ ) on the grid (see Figure 5.1).
4. Set the position BEGIN to this probe location.
5. Exit Terminal Mode and restart Dashboard. Use the mouse to push RESET button and then the GO button. This will place the miniature E-field probe above the UniHead in its start position.
6. From the Application Menu select FLATSAR.XLS. Microsoft Excel will open this file automatically.
7. Enter a name for the spreadsheet that will be created with the measurement data. The file name should include the DUT model number, measurement height, "zoom" and date.
8. Select the scan resolution of 5 mm. The default x and y spans are 8 cm. If other scan resolutions or spans are desired, then the Visual Basic code will have to be edited.
9. Start the scan by pushing the ACQUIRE DATA button with the mouse pointer. The application will now run automatically and acquire the data.

10. Once the application has stopped, quit the application. Reenter Terminal mode and change the tool transform to REF75. Type STATUS and verify that the tool transform in effect is REF75.
11. Repeat steps 5-9. This create a spreadsheet with a second scan data set 0.5 cm further away from the surface of the phantom.
12. Once the application has stopped, quit the application. Reenter Terminal mode and change the tool transform to REF125. Type STATUS and verify that the tool transform in effect is REF125.
13. Repeat steps 5-9. This creates another spreadsheet with a third scan data set an additional 0.5 cm further away from the surface of the phantom. Once the application has stopped, quit the application.
14. Print out the surface and contour plots for each of the 3 spreadsheets.

### 6.3 1g and 10 g averaging

1. Open the PEAK SAR.XLS template and resave it with a new name that should include the DUT model number, "peak SAR" and date
2. Modify the formulas in the 1g and 10 g averaging sheets to gather data from the 3 zoom scan spreadsheets. A numerical procedure will then search for the 1-cm<sup>3</sup> or 8-cm<sup>3</sup> cube with the highest average SAR within this data array.
3. Note the location of the peak 1g or 10 g SAR and the (x,y) coordinates of the center and the 4 edges.
4. Use the mouse pointer to push RESET button on Dashboard and then the GO button. This will place the miniature E-field probe above the UniHead in its start position.
5. From the Application Menu select FLATSAR.XLS. Microsoft Excel will open this file automatically. Enter the name "TEMP" for the spreadsheet that will be created.
6. Use <ALT>-<TAB> to switch to back to RobComm.
7. Close Dashboard, put RobComm in Terminal mode and change the tool transform to REF25. Type STATUS and verify that the tool transform in effect is REF25.
8. Move the probe to the (x,y) coordinates corresponding to the center of the peak SAR cube.
9. Use <ALT>-<TAB> to switch to back to TEMP.XLS
10. Use the mouse pointer to push the "Single Point" button. Record the values displayed in the last 3 columns for the 3 probe sensors.
11. Use <ALT>-<TAB> to switch to back to RobComm.
12. Move the probe to the next (x,y) coordinates corresponding to the east edge of the peak SAR cube.
13. Repeat steps 9-11.
14. Move the probe to the next (x,y) coordinates corresponding to the south edge of the peak SAR cube.

15. Repeat steps 9-11.
16. Move the probe to the next (x,y) coordinates corresponding to the west edge of the peak SAR cube.
17. Repeat steps 9-11.
18. Move the probe to the next (x,y) coordinates corresponding to the north edge of the peak SAR cube.
19. Repeat steps 9-11.
20. Use <ALT>-<TAB> to switch back to RobComm.
21. Change the tool transform to REF50. Type STATUS and verify that the tool transform in effect is REF50.
22. Repeat steps 8 through 20.
23. Change the tool transform to REF50. Type STATUS and verify that the tool transform in effect is REF50.
24. Repeat steps 8 through 20.
25. Change the tool transform to REF75. Type STATUS and verify that the tool transform in effect is REF75.
26. Repeat steps 8 through 20.
27. Change the tool transform to REF100. Type STATUS and verify that the tool transform in effect is REF100.
28. Repeat steps 8 through 20.
29. Change the tool transform to REF125. Type STATUS and verify that the tool transform in effect is REF125.
30. Repeat steps 8 through 20.
31. Change the tool transform to REF150. Type STATUS and verify that the tool transform in effect is REF150.
32. Repeat steps 8 through 20.
33. Change the tool transform to REF175. Type STATUS and verify that the tool transform in effect is REF175.
34. Repeat steps 8 through 20.
35. Quit TEMP.XLS.
36. Enter the data obtained above into sheets Sensor1, 2 and 3 of the spreadsheet created in step 1.
37. A numerical procedure will process the data create a chart of the 5 exponential curve such as shown in Figure 6.1. The average of the exponential coefficients is then used to extrapolate the 1 g or 10 g peak SAR to the surface.

Figure 6.1
