

## 8.0 FCC RF Exposure Limitations

# Compliance with the RF Exposure Limitations for the VHDD-550S

Peak Power = 550kW

Pulse Width = 2.0  $\mu$ s

Pulse Repetition Frequency = 500 Hz

Average Power (P) = 550W

Wavelength ( $\lambda$ ) = 10.71 cm (S-Band Wavelength)

Reflector Diameter (D) = 8 m

Reflector Surface Area (A) = 50.26 m square

Reflector Isotropic Gain = 45 dBi

Given that the above parameters are fixed, the power density is a function of range and location with regard to the axis of the main beam. The power density is greatest along the main beam axis, so all calculations will be made for this condition.

Three different methods are used to estimate power density, depending on whether the point of interest is in the near-field region, the transition region, or the far-field region of the antenna. For  $\lambda$  = 10.71 cm, the near field region extends to 149.39 m (490.12 ft), the transition region extends to 298.78 m (980.25 ft) and the far-field region extends from this point.

$$R_{nf} = D^2 / 4\lambda \quad \text{or} \quad 149.39 \text{ meters}$$

$$R_{ff} = 2D^2 / 4\lambda \quad \text{or} \quad 298.78 \text{ meters}$$

Within the near-field region the power density can reach a maximum of 131480.82 mw/cm<sup>2</sup> at the front of the antenna.

The power density decreases inversely with the distance from the antenna within the transition region. At the start of the transition region the power density is 5.617 mw/cm<sup>2</sup>. Near the end, (298.78 m) the power density is 1.491 mw/cm<sup>2</sup>.

Beyond 298.78 m (838.58 ft), the power density can be calculated as follows.

$$S = PG / (4\pi R^2)$$

Where S is power density, P is power, G is antenna gain and R is distance from the antenna.

Utilizing this equation, we can solve for the distance at which the power density is below the FCC controlled exposure limit of  $5 \text{ mw/cm}^2$ . This distance is 162 m (531.5 ft). We can also solve for the distance at which the power density is below the FCC uncontrolled exposure limit of  $1 \text{ mw/cm}^2$ . This distance is 364 m (1194 ft)

If the point of interest is beyond 1194 ft, then the power density is such that it is below the uncontrolled exposure limit. **This is even if the point of interest remains on-axis at all times because the antenna is not rotating.**

If the point of interest is at least one antenna diameter (8m) off-axis within the near field or transition region, the power density is at least a factor of 100 less than the values calculated above. The tower height should be such that the main beam is 10m above ground level at 200m distance when the main beam is pointing 1 degree below the horizon. Therefore, the tower should be at a minimum:

$$10\text{m} + 3.5\text{m} + 8\text{m} = 21.5\text{m} (70.54 \text{ ft})$$

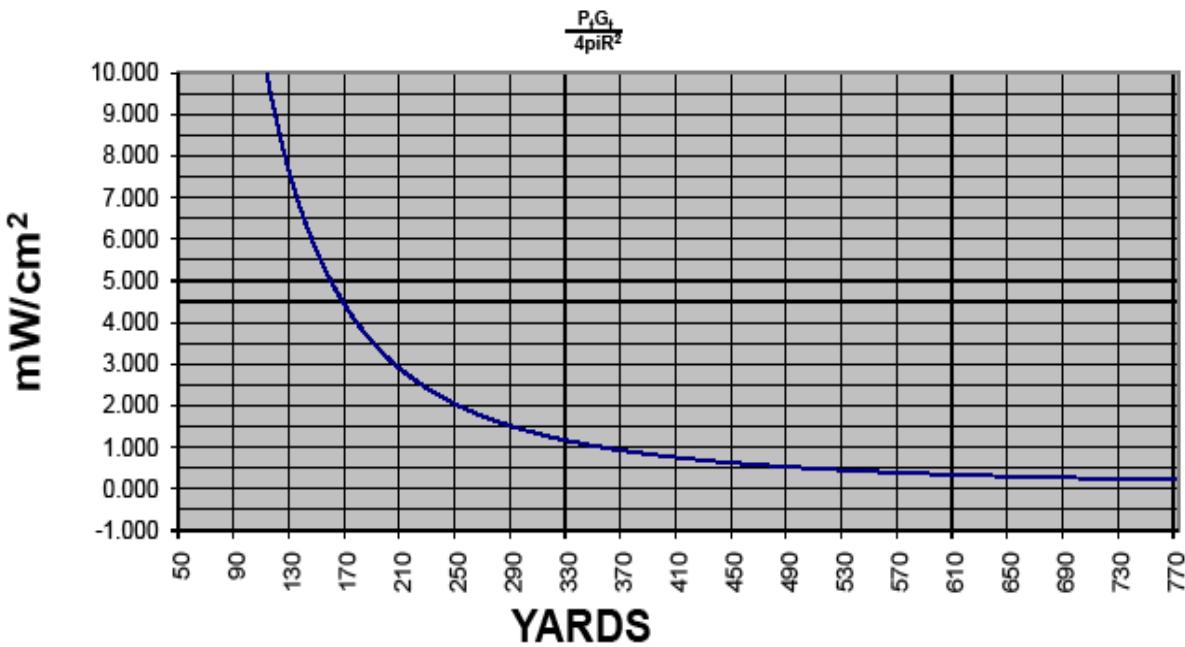

At this height, all points along the ground (near-field included) will have a power density below the FCC controlled limit of  $5 \text{ mw/cm}^2$ .

One item not considered is that exposure limits may be averaged (6 minutes for controlled access and 30 for uncontrolled access.) The fact that the antenna is rotating and a fix point of interest is on-axis for only a brief period of time (factor of .0027), greatly reduces the average power density. Thus, **all** points of interest not on the antenna surface are below both exposure limits while the antenna is rotating.

In conclusion, a radar system with the above characteristics can be within compliance with FCC exposure limit guidelines by mounting the antenna 70ft or higher above any occurred areas within 531ft of the antenna.
