

### **iRM4451 Tune-up procedure**

Each iRM4451 unit is subject to an automated RF Calibration as part of system test during manufacture.

As part of the test, the RF output power level for each port is measured at a number of gain settings in order to calibrate the internal power measurement and then provide accurate power control.

The calibration data required to do this are unique to each unit and recorded and loaded on the unit as part of the automated system test.

The permitted power tolerance is +0.5 / -0.5dB.
