FCC ID: 02SNURIT3010RT
Applicant: Lipman USA Inc.
Equipment: Wireless POS EDC Terminal
Model: Nurit 3010 with a RIM R902-M-2-0 modem and a TNC Carrant Antenna
Standard: FCC 96 –326, Guidelines for Evaluating the Environmental Effects of Radio-Frequency Radiation

ENGINEERING SUMMARY

This report contains the results of the engineering evaluation performed on a Lipman Nurit 3010 EDC point of sale terminal which incorporates a RIM Mobitex R902M-2-0 modem. The measurements were carried out in accordance with FCC 96-326. The wireless desktop device was evaluated for its maximum power level (ERP 2.239 W). The duty factor of the radio modem is intrinsically restricted to 25% (See Appendix E).

The wireless desktop device was tested at low, middle and high channels for the left, right, and keyboard up sides, with the antenna at the 0, 90, and 180 degree positions. The maximum 10g SAR (0.56 W/kg) was found to coincide with the peak performance RF output power of channel 0720 (middle, 899 MHz) for the left side of the device, with the antenna in the 90 degree position. (The hot spot is located on the antenna). At a separation distance of 0 cm from the antenna of the device, the maximum 1g SAR is 0.99 W/kg. Test data and graphs are presented in this report.

Based on the test results and on how the device will be marketed and used, it is certified that the product meets the requirements as set forth in the above specifications, for uncontrolled RF exposure environment.

(The results presented in this report relate only to the sample tested.)

1. INTRODUCTION

Tests were conducted to determine the Specific Absorption Rate (SAR) of a sample of a Lipman Nurit 3010 EDC point of sale terminal which incorporates a RIM Mobitex R902M-2-0 modem. These tests were conducted at APREL Laboratories' facility located at 51 Spectrum Way, Nepean, Ontario, Canada. A view of the SAR measurement setup can be seen in Appendix A Figure 1. This report describes the results obtained.

2. APPLICABLE DOCUMENTS

The following documents are applicable to the work performed:

- 1) FCC 96-326, Guidelines for Evaluating the Environmental Effects of Radio-Frequency Radiation
- 2) ANSI/IEEE C95.1-1999, IEEE Standard for Safety Levels with Respect to Human Exposure to Radio Frequency Electromagnetic Fields, 3 kHz to 300 GHz.
- 3) ANSI/IEEE C95.3-1992, IEEE Recommended Practice for the Measurement of Potentially Hazardous Electromagnetic Fields – RF and Microwave.
- 4) OET Bulletin 65 (Edition 97-01) Supplement C (Edition 97-01), "Evaluating Compliance with FCC Guidelines for Human Exposure to Radio Frequency Electromagnetic Fields".

3. DEVICE UNDER INVESTIGATION

- Lipman Nurit 3010 EDC point of sale, s/n 86U10-5913442, which incorporates a RIM Mobitex R902M-2-0 modem received on 28 November, 2000.

The Lipman Nurit 3010 EDC point of sale will be called DUI (Device Under Investigation) in the following.

The DUI is intended to be used as a desktop device which operates in the frequency band of 896 MHz - 901 MHz. The antenna of the DUI is omnidirectional with a TNC connector. The DUI nominally transmitted with a 25% duty factor. See the manufacturer's submission documentation for drawings and more design details.

4. TEST EQUIPMENT

- APREL Triangular Dosimetric Probe Model E-009, s/n 115, Asset # 301420
- CRS Robotics A255 articulated robot arm, s/n RA2750, Asset # 301335
- CRS Robotics C500 robotic system controller, s/n RC584, Asset # 301334
- APREL F-2, flat manikin, s/n 002
- Tissue Recipe and Calibration Requirements, APREL procedure SSI/DRB-TP-D01-033
- HP 438A power meter, s/n 2502A01684, Asset # 301417
- HP 8482A power sensor, s/n 2652A1512B, Asset # 301418

5. TEST METHODOLOGY

1. The test methodology utilised in the certification of the DUI complies with the requirements of FCC 96-326 and ANSI/IEEE C95.3-1992.
2. The E-field is measured with a small isotropic probe (output voltage proportional to E^2).
3. The probe is moved precisely from one point to the next using the robot (10 mm increments for wide area scanning, 5 mm increments for zoom scanning, and 2.5 mm increments for the final depth profile measurement).
4. The probe travels in the homogeneous liquid simulating human tissue. Appendix A contains information about the properties of the simulated tissue used for these measurements.
5. The liquid is contained in a manikin simulating a portion of the human body.
6. The DUI is positioned with the surface under investigation against the phantom.
7. All tests were performed with the highest power available from the sample DUI under transmit conditions.

More detailed descriptions of the test method is given in Section 6 when appropriate.

5. TEST RESULTS

5.1. TRANSMITTER CHARACTERISTICS

The battery-powered DUI will consume energy from its batteries, which may affect the DUI’s transmission characteristics. In order to gage this effect the output of the transmitter is sampled before and after each SAR run. In the case of this DUI, the conducted power was sampled. The following table shows the conducted RF power sampled before and after each of the eight sets of data used for the worst case SAR in this report.

Scan		Power Readings (dBm)		D (dB)	Battery #
Type	Height (mm)	Before	After		
Area	2.5	-1.68	-1.68	0	3
Area	12.5	3.08	3.08	0	1
Zoom	2.5	3.08	3.08	0	2
Zoom	7.5	3.08	3.08	0	1
Zoom	12.5	3.08	3.08	0	3
Zoom	17.5	3.08	3.08	0	4
Zoom	22.5	3.08	3.08	0	2
Depth	2.5 – 22.5	3.08	3.08	0	4

Table 1. Sampled Conducted RF Power

5.2. SAR MEASUREMENTS

- 1) RF exposure is expressed as a Specific Absorption Rate (SAR). SAR is calculated from the E-field, measured in a grid of test points as shown in Appendix A Figure 1. SAR is expressed as RF power per kilogram of mass, averaged in 10 grams of tissue for the extremities and 1 gram of tissue elsewhere.
- 2) The DUI was put into test mode for the SAR measurements via communications software supplied by the radio manufacturer running on a PC to control the channel and maximum operating power (ERP 2.239 W). The duty factor was 25% .
- 3) Figure 3 in Appendix A shows a contour plot of the SAR measurements for the DUI (channel 0720, middle, 899 MHz, left side, antenna extended at 90 degrees). It also shows an overlay of the DUI's outlines, superimposed onto the contour plot. The presented values were taken 2.5mm into the simulated tissue from the flat phantom's solid inner surface. Figures 1 and 2 show the flat phantom used in the measurements. For the left side measurements, the antenna of the DUI was aligned with $x=10$ and the bottom edge of the DUI, with $y=20$.

A different presentation of the same data is shown in Appendix A Figure 3. This is a surface plot, where the measured SAR values provide the vertical dimension, which is useful as a visualisation aid.

- 4) Wide area scans were performed for the low, middle and high channels on the left, right, and keyboard up sides of the DUI, with the antenna at the 0, 90, and 180 degree position (See Figure 1 in Appendix A). The DUI was operating at maximum output power (2W / 33dBm) and 25% duty factor. The peak single point SAR for the scans were:

TYPE OF EXPOSURE	DUI side	Antenna Position in Degrees	Antenna distance to phantom (mm)	Channel			Peak Local SAR (W/kg)
				L/M/H	#	Freq (MHz)	
Hand\Bystander	Left side	90	0	High	0880	901	0.80
	Left side	90	0	Middle	0720	899	0.99
	Left side	90	0	low	0480	896	0.78
	Left side	0	0	High	0880	901	0.52
	Left side	180	0	High	0880	901	0.61
	Keyboard up	0	N/A	Middle	0720	899	0.03
	Right side	0	N/A	Middle	0720	899	0.03

Table 2. SAR Measurements

6. USER’S HAND EXPOSURE

All subsequent testing for user’s hand exposure was performed on channel 0720 (middle, 899 MHz), with the left side of the DUI facing up against the bottom of the phantom and the antenna touching the phantom in the 90 degree position. This relates to the position and frequency found to provide the maximum measured SAR value.

- 1) Channel 0720 (middle, 901 MHz) was then explored on a refined 5 mm grid in three dimensions. The SAR value averaged over 10 grams was determined from these measurements by averaging the 125 points (5x5x5) comprising a 2 cm cube. The maximum SAR value measured averaged over 10 grams was determined from these measurements to be 0.30 W/kg.
- 2) To extrapolate the maximum SAR value averaged over 10 grams to the inner surface of the phantom a series of measurements were made at five (x,y) co-ordinates within the refined grid as a function of depth, with 2.5 mm spacing. The average exponential coefficient was determined to be $(-0.13 \pm 0.01) / \text{mm}$.

- 3) The distance from the probe tip to the inner surface of the phantom for the lowest point is 2.5 mm. The distance from the probe tip to the tip of the measuring dipole within the APREL Triangular Dosimetric Probe Model E-009 is 2.3 mm. The total extrapolation distance is 4.8 mm, the sum of these two.

Applying the exponential coefficient over the 4.8 mm to the maximum SAR value averaged over 10 grams that was determined previously, we obtain the **maximum SAR value at the surface averaged over 10 grams, 0.56 W/kg**.

7. BYSTANDER EXPOSURE

- 1) Channel 0720 (middle, 899 MHz) was also explored on a refined 5 mm grid in three dimensions. The SAR value averaged over 1 gram was determined from these measurements by averaging the 27 points (3x3x3) comprising a 1 cm cube. The maximum SAR value measured averaged over 1 gram was determined from these measurements to be 0.52 W/kg.
- 2) To extrapolate the maximum SAR value averaged over 1 gram to the inner surface of the phantom a series of measurements were made at five (x,y) coordinates within the refined grid as a function of depth, with 2.5 mm spacing. The average exponential coefficient was determined to be $(-0.13 \pm 0.01) / \text{mm}$.
- 3) The distance from the probe tip to the inner surface of the phantom for the lowest point is 2.5 mm. The distance from the probe tip to the tip of the measuring dipole within the APREL Triangular Dosimetric Probe Model E-009 is 2.3 mm. The total extrapolation distance is 4.8 mm, the sum of these two.

Applying the exponential coefficient over the 4.8 mm to the maximum SAR value averaged over 1 gram that was determined previously, we obtain the **maximum SAR value at the surface averaged over 1 gram, 0.99 W/kg**.

8. CONCLUSIONS

The maximum Specific Absorption Rate (SAR) averaged over 10 grams, determined at 899 MHz (middle channel, 0720, left side, 2W / 33dBm) of the Lipman Nurit 3010 EDC point of sale terminal, which incorporates a RIM Mobitex R902M-2-0 modem is 0.56 W/kg. The overall margin of uncertainty for this measurement is $\pm 24.3\%$ (Appendix B). The SAR limit given in the FCC 96-326 Safety Guideline is 4 W/kg for uncontrolled hand exposure for the general population. This SAR limit reduced by the measurement uncertainty (4.0 - 24.3%) is 3.03 W/kg.

For a bystander or user exposing a part of the body other than the extremities, at a separation distance of 0 cm from the device, the maximum Specific Absorption Rate (SAR) averaged over 1 g is 0.99 W/kg. The SAR limit given in the FCC 96-326 Safety Guideline is 1.6 W/kg for uncontrolled partial body exposure of the general population. This SAR limit reduced by the measurement uncertainty (1.6 - 24.3%) is 1.21 W/kg.

Considering the above, this unit as tested, and as it will be marketed and used, is found to be compliant with the FCC 96-326 requirement.

Tested by *K. B.* Date JAN 25, 2001

APPENDIX A. Measurement Setup, Tissue Properties and SAR Graphs

Figure 1. Setup

Simulated muscle Tissue Material and Calibration Technique

The mixture used was based on that presented SSI/DRB-TP-D01-033, “Tissue Recipe and Calibration Requirements”. The density used to determine SAR from the measurements was the recommended 1040 kg/m³ found in Appendix C of Supplement C to OET Bulletin 65, Edition 97-01).

Dielectric parameters of the simulated tissue material were determined using a Hewlett Packard 8510 Network Analyser, a Hewlett Packard 809B Slotted Line Carriage, and an APREL SLP-001 Slotted Line Probe.

	APREL	OET 65 Supplement	Δ (%) (OET)
Dielectric constant, ϵ_r	51.6	55.96	-7.8%

APPENDIX E. Duty Factor Limiting Algorithm for the OEM Radio Module R902M-2-O

The duty factor limiting algorithm for the OEM radio module R902M-2-O is a firmware algorithm that directly inhibits the radio firmware that generates transmit pulses. This algorithm will be permanently integrated with the radio firmware and installed at time of manufacture in the production facility. The algorithm cannot be modified or disabled by the user.

The radio module operates on a packet data network. The network controls the timing of most aspects of the radio signalling protocol. The shortest transmit event over which the mobile device has timing control is an entire uplink (transmit) transaction which is a series of transmit pulses. From the perspective of the mobile device this is an “atomic” event, i.e. the network controls the timing of the signalling within the transaction and the transaction can not be broken into smaller independent sub-parts.

Research in Motion Ltd. has implemented and tested a duty factor limiting algorithm for the radio module to comply with the requirement for limiting the duty factor at all times. To limit the duty factor at all times the algorithm controls the timing of when uplink (transmit) transactions are initiated. When an uplink (transmit) transaction occurs the algorithm accrues the actual transmit time. The algorithm ensures that the idle (transmitter off) time is sufficient to ensure the duty factor is less than the limit (25%) before the next uplink (transmit) transaction is initiated. This ensures that the duty factor is limited to the maximum allowable over all times.
