Test Procedure

The processing gain is measured using the CW jamming margin method. A signal generator producing a CW Jammer signal (J) is stepped in 50 kHz increments across the 10 MHz pass band of the system. At each point the CW Jammer Signal generator level required to produce a Bit Error Rate equivalent to $BER = 10E-5$ is recorded as the Jammer level (J). The output power of the PRISM ref. transmitter is fixed at -62.0 dBm (which is about 20.0 dB above RX sensitivity threshold) and referred to as Signal (S). The Jammer to Signal ratio (J/S) is then calculated and recorded with 20% of the worst data points discarded. The lowest remaining (J/S) ratio is referred to as Mj and is used to calculate the processing gain (PG) using the following formula:

$$PG = (S/N)_o + M_j + L_{sys}$$

With:

$L_{sys} = 2.0$ dB and

$(S/N)_o$ as derived from data sheet of DSSS chipset.
