Terms and Definitions

- **Subset:** A predefined group of radiating elements that are excited simultaneously with same amplitude and possibly different phases. There are three Subsets, and each one of them includes between 10 to 12 of the 24 elements of RFEM 3. The Subsets are also called Sub-Arrays.
- **Beamforming Code:** A configuration of phase-shifter values for all of the elements in a specific Subset. The Beamforming Code is used in order to direct the antenna to a desired spatial direction.
- **Sector:** A predefined set of Beamforming Codes, used for automatic selection of the Subset to be used.

1 Document Scope

1.1 Introduction

This report is submitted to support the compliance with the FCC rule located in Title 47 of the Code of Federal Regulations (CFR), parts §2.1093 and §15.255(f), of Intel 18265NGW WiGig module (FCC ID: PD918265NG), including an active antenna array, embedded inside the Dell model P73G.

Per the location of the active antenna array (a.k.a. RFEM 3) in the Dell model P73G platform, the distance between the antenna arrays to the body of an end user, at the closest contact point, will be in the near field.

In order to prove that during typical use the energy goes in most cases away from the human body, several tests of beamforming behavior were performed under different use cases conditions. The results are presented in this document.

These tests are supported by a determination of the near-field power average density performed using an EM simulation supported by a near field measurement. An EM simulation that includes the RFEM 3 transmitter model embedded inside the Dell model P73G is used to determine the worst case configuration and the correspondent near field power density. This worst case power density is considered as a conservative case because the energy is always oriented toward the human body, this latter is also supported by near field measurements. Due to the range of variations and uncertainty introduced by measurement and simulation, the results can only be applied to supplement each other, in conjunction with the beamforming mitigation results, through qualitative comparison and extrapolation to establish compliance at the device surface.

The simulation method, simulation results, and near field measurement results are described in this document. The near field measurement system details are described in document [2] and the comparison between simulation and measurement is shown in [3].

Chapter 2 provides relevant background on Intel 18265NGW module. Chapter 3 shows the results of the beamforming behavior in operational mode directing the energy away from body. Appendix A describes the simulation methodology to determine the worst case configuration and the power density simulation results.

2 Background – WiGig System Operation

2.1 System Block Diagram

The Intel 18265NGW module is a solution for WiGig connectivity for various platforms. The Intel 18265NGW module can be embedded in a conventional clamshell PC (such as the Dell model P73G) as well as in modern 2-in-1 (detachable) platforms and tablet-like platforms.

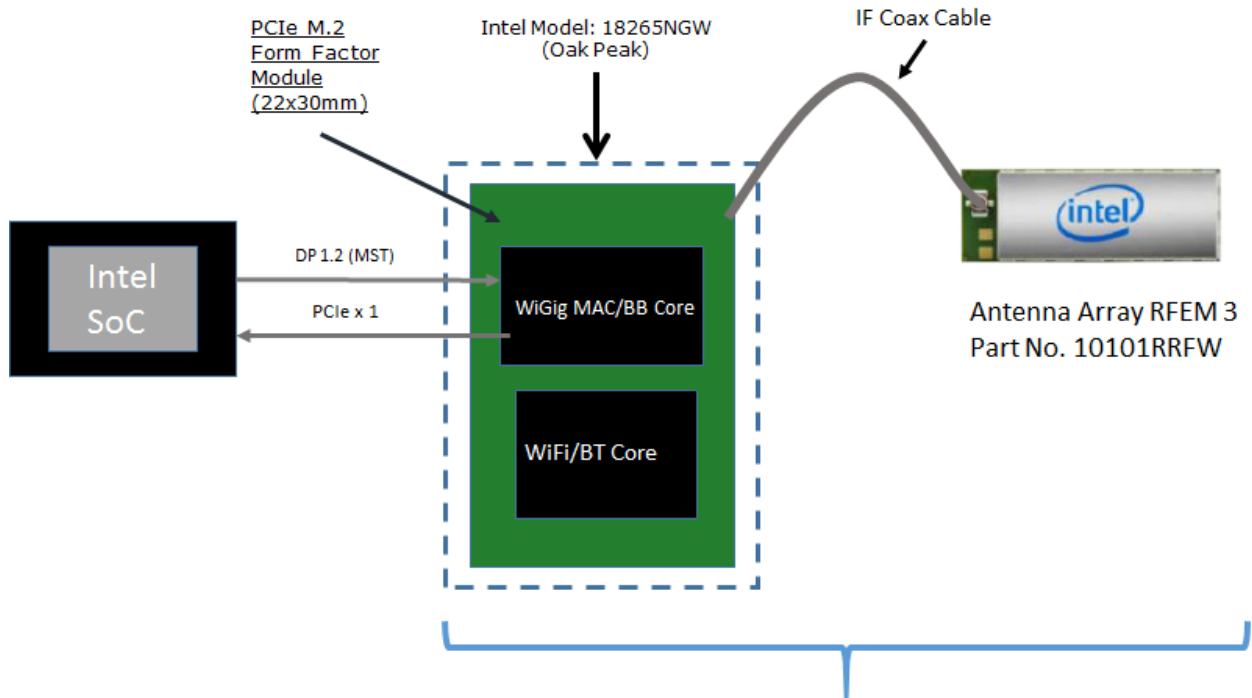

The client solution for Dell P73G includes the 18265NGW WiGig module (FCC ID: PD918265NG) connected to a beam forming antenna array RFEM 3 using one IF coaxial cable.

The WiGig module (FCC ID: PD918265NG) is a PCIe M.2 module consisting of a WiGig BB chip, which implements the WiGig MAC, Modem, BF algorithm, and active antenna array module control, as well as the BB + IF stage circuitry. Intel calls this module Oak Peak. (Note that Oak Peak uses the same WiGig base band silicon as Maple Peak.)

RFEM 3 (10101RRFW) is an active antenna array module, which converts the IF signal to a 60 GHz signal. It also performs the beam forming functionality by phase¹ shifting the RF signal that goes to each antenna. The RFEM 3 is slave to the WiGig BB chip, since all module control and algorithms run on the BB chip.

Intel System-on-Chip (SoC) houses the central processing unit (CPU), which executes applications and provides command and control of the client solution, including all I/O data and addressing.

¹ Each antenna is excited by an amplitude at a defined phase angle. RFEM 3 feeding circuit has 2 bit phase shifter. Therefore, the phase's values can be 0, 90, 180, or 270 degrees.

Client Solution includes Oak Peak module
IF Coax Cable and antenna array RFEM 3 (10101RRFW)

Figure 1 – Intel 18265NGW module system block diagram

Note: Also known by Intel internal project code name “Oak Peak,” the above-described WiGig module solution still uses the “Maple Peak” Intel chipset (both MAC/BB chip and radio chip).

2.2 Beamforming

Achieving high-bandwidth communication over 60 GHz channels usually requires directional antennas at the transmitter and receiver sides. In consumer electronics, fixed directional or mechanically-rotated antennas are not practical, and electronically steerable antennas are usually used.

In the Intel 18265NGW module, an electronically-steerable antenna array is used. Beam forming protocol (defined in the IEEE 802.11ad standard) is used to find the right direction for setting both the RX and TX antenna directions.

Due to the RFEM structure, it is not easy to predict the direction and beam forming combination that yields the maximum energy in near field. To find this value, a search over the possible beam forming combination was made and the worst case value was taken. A detailed explanation of this process can be found in Section A.1.4.

2.3 TX Duty Cycle

The WiGig protocol, as defined in ISO/IEC/IEEE 8802-11:2012/Amd.3:2014(E), Clause 21, is packet-based, with time division multiplexing (TDM). The Intel 18265NGW module is configured to guarantee that the TX-Duty-Cycle, defined as the ratio of the duration of all transmissions to the total time, is at most 70% over any 10-second period. This was established by worst-case analysis, as derived from full-system simulation, and verified by measurements.

The limited TX-Duty-Cycle is established based on HW and FW implementation with a measurement interval of ~100 ms (102.4 ms) and 10-second averaging; other details are provided in reference [1]. The 70% duty cycle limitation is guaranteed, independent of user activity, and therefore adheres to the source-based time-averaging definition in Title 47 of the Code of Federal Regulations (CFR) 2.1093(d)(5).

In addition, measurements of the Intel 18265NGW module, configured to obtain maximal TX-Duty-Cycle in a fully loaded system, resulted in an actual maximum TX-Duty-Cycle of 58% over any 10-second period, lower than the upper bound derived from the analysis in this section.

2.4 Intel 18265NGW module in Dell model P73G

Intel produces several HW SKUs (variations) of the Intel 18265NGW module, which target different types of customer platform products.

Dell uses the Intel 18265NGW module inside the Dell model P73G platform. This SKU is characterized by

1. Supporting channels **1+2+3**
2. Reduced power emission, which translates to
 - a. Maximum transmit conducted power of **5.5 dBm** aggregated conducted power at the antenna ports.
 - b. Maximum TX duty-cycle of **70%**.

3 Beamforming Behavior in Operational Mode

3.1 Introduction

The goal of this section is to show that during typical use of RFEM 3 inside Dell Model P73G, the energy would go away from the human body. This will be showed by performing several beamforming behaviour tests taking into account different typical heights, distances and EUT orientation.

3.2 Environmental Conditions

At the site where the measurements were performed the following limits were not exceeded during the tests:

Temperature	21°C ± 1°C
Humidity	30% ± 10%

3.3 Test samples

Sample	Control #	Description	Model	Serial Number	Date of receipt
#01	161114-01.S03	Wireless Module installed in conventional laptop	18265NGW inside P73G	N/A	2016-12-12
	161114-01.S04	AC Adapter	NA	CN-06C3W2-72438-69N-0B54-A03	2016-12-12

3.4 EUT Features

Brand Name	Intel Model 18265 inside Dell Model P73G	
Model Name	Client Platform Design Guidelines	
FCC/IC ID	FCC ID: PD918265NG/IC ID: 1000M-18265NG	
Software Version	3.0.41131.1	
Prototype / Production	Production	
Host Identification	P73G series	
Exposure Conditions	Localized free space power density	
Supported Radios	WiGig	60GHz (57.24 – 63.72 GHz)
	802.11b/g/n	2.4GHz (2400.0 – 2483.5 MHz)
	802.11a/n/ac	5.2GHz (5150.0 – 5250.0 MHz)
		5.3GHz (5250.0 – 5350.0 MHz)
		5.6GHz (5470.0 – 5725.0 MHz)
		5.8GHz (5725.0 – 5825.0 MHz)
Bluetooth	2.4GHz (2400.0 – 2483.5 MHz)	
Antenna Information	RFEM3 (10101RRFW)	

Note: RF exposure compliance for 802.11 and Bluetooth capabilities are not addressed in this document neither the associated documents mentioned in section 1.2..

3.5 Test System Description

As mentioned in the introduction, the goal of this measurement is to prove that energy goes away from the body when the EUT is at its proximity. The metric that can show this behaviour is the percentage of operation of each subset.

The tests are performed with four EUT orientations:

- Case 1: EUT placed horizontally over lap. Lid open at 110°.
- Case 2: EUT placed horizontally with a lateral shifting to the side of the Lap. Lid open at 110°.
- Case 3: EUT placed horizontally over lap. Lid open at 160°.
- Case 4: EUT placed horizontally with a lateral shifting to the side of the Lap. Lid open at 160°.

The next sections, present the test setup, test configuration and measurement results for the four cases listed above.

3.5.1 Antenna System and Measurement setup

3.5.1.1 Antenna System

Figure 2 illustrates the position of the RFEM 3 antenna when the EUT is placed horizontally (Case 1-4). All test configurations are defined in Table 3. The same figure shows the nominal beam direction of each subset. For all cases, the tests should prove that subset 1 or subset 3 is operational in the majority of time when the DUT is close to the body in order to direct the beam away from the body.

- * Subset 2 directed towards the body
- * Subset 1 and Subset 3 directed away from the body

Figure 2– RFEM 3 Subsets nominal beam directions

Note that when a subset is operational, a beamforming code (phases’ combination of the subset’s elements) among a set of codes (instances) for each subset is realized.

Table 2 illustrates the sectors numbers associated to each subset. The 62 sectors were designed to achieve sufficient coverage in all spatial directions.

Table 2 – Subsets’ sectors

Number of Sector															
1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	32
33	34	35	36	37	38	39	40	41	42	43	44	45	46	47	48
49	50	51	52	53	54	55	56	57	58	59	60	61	62		
Subset 1				Subset 2				Subset 3							

The second parameter to be studied in these tests is the existence of a transition zone in which a handover from subset to another is observed. This is essential to prove the efficiency of the beamforming algorithm.

3.5.1.2 Measurement Setup

- The dock station is placed on the table with a height of 80 cm above the horizontal office floor.
- The person is holding the EUT horizontally on his lap.

- Initially, the EUT is touching the person's lap at the evaluation plane as shown in Figure 3. In this case, the dock station and the EUT are at the same height i.e. 80 cm above the horizontal office floor.

Figure 3– Qualitative measurement test setup

3.6 Test configuration

For each test case, the test configuration is described as follow:

- The EUT and the dock station are set in operational mode and a link condition between the two devices is made using a link software used with Dock and host model P73G in normal operational mode (Wireless Dock Manager, Version 3.0.41131.1).

- The measurement is performed at two distances (d) between the dock station and the EUT i.e. 45 cm and 90 cm. These distances represent two typical use cases of the Laptop.
- For each distance (d) the test is performed for several heights (h) between the EUT exposure's plane with and without a horizontal offset (lateral shifting) of the platform to the side of the user's lap. The height is modified (Figure 5) as described below
 - (1) The EUT is raised from the lap position ($h=0$) until a transition height ($h=h_t$) where a handover between subsets is observed, if applicable. The handover is a drop of % below 80% for the given subset.
 - (2) The EUT height is increased until it has passed the transition region in which a handover from a subset to another is observed
 - (3) The EUT is moved back toward the lap in reverse order until it has passed the lower boundary of the transition region.
- Styrofoam spacers with specific heights are used between the EUT and the person lap's (Figure 4)
- Beam forming triggering in operational mode: when the link is not in maximum MCS¹ (MCS 12) the SW triggers beam forming each 4 seconds.
- In case of abrupt MCS degradation (3 MCS steps) compared to the chosen MCS, or no response from the other side, then there is immediate beam forming triggering. For each EUT position, the measurement time is selected to be sufficient for conditions to stabilize and to record the beamforming code instances. When connection is dropped, the device starts a search phase in which it normally transmits for less than 1ms once per 1 second (<0.1%). Additional transmissions happen only if it finds another device and they start to connect to each other.

Figure 4– Qualitative measurement test configuration

1: MCS stands for Modulation and Coding Scheme, and it controls the PHY data rate being used per packet. Data MCS ranges between 1 and 12, and the higher the MCS is the higher data rate. The beamforming aims to improve the link conditions. If the MCS is MCS-12, then data-rate is maximal, there's no option to further improve the link, and therefore beamforming is not triggered.

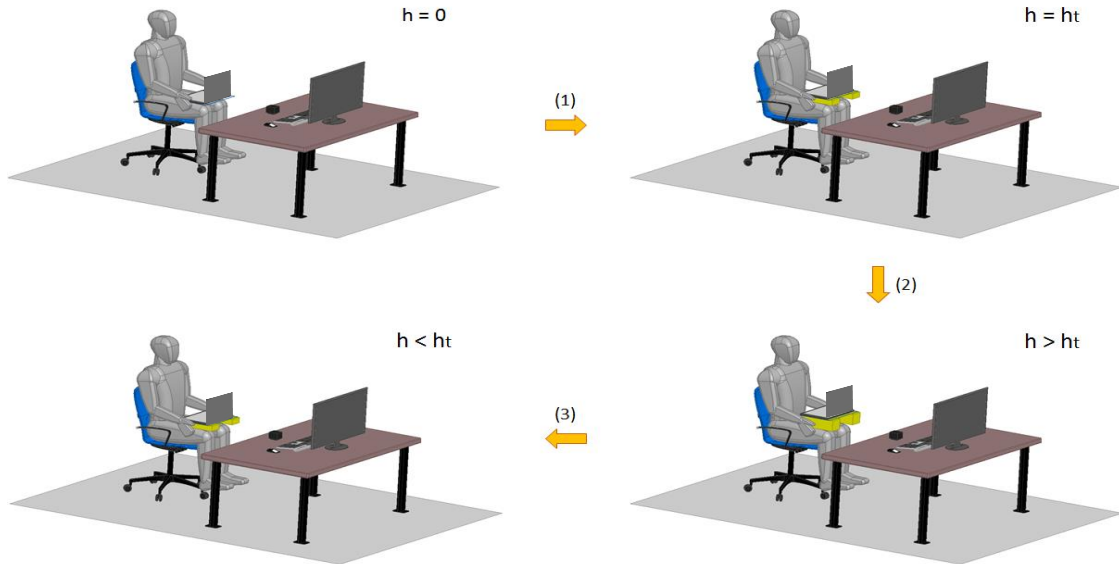

Figure 5– Height variation for transition zone determination

Table 3 summarizes the realized test configurations.

Table 3 – Test configuration summary – EUT placed horizontally on lap

Test number	EUT to dock station distance (d)	Transverse transition	Lid opening angle	EUT to person laps distance (h)
1	45 cm	No	110°	0, 2, 4, 6, 8, 10, 12, 14, 16 and 20 cm
2	90 cm	No	110°	0, 2, 4, 6, 8, 10, 12, 14, 16 and 20 cm
3	45 cm	Yes	110°	0, 2, 4, 6, 8, 10, 12, 14, 16 and 20 cm
4	90 cm	Yes	110°	0, 2, 4, 6, 8, 10, 12, 14, 16 and 20 cm
5	45 cm	No	160°	0, 2, 4, 6, 8, 10, 12, 14, 16 and 20 cm
6	90 cm	No	160°	0, 2, 4, 6, 8, 10, 12, 14, 16 and 20 cm
7	45 cm	Yes	160°	0, 2, 4, 6, 8, 10, 12, 14, 16 and 20 cm
8	90 cm	Yes	160°	0, 2, 4, 6, 8, 10, 12, 14, 16 and 20 cm

3.7 Test results

3.7.1 Case 1: EUT placed horizontally on lap, Lid open at 110°

Figure 6 and Figure 7 show the test results of the subset operation according to the EUT to lap distance (h), for the two horizontal distances: 45 and 90 cm respectively, when the Lid is open at 110°. The x-axis represents the height above lap while the y-axis represents, for each subset, the percentage of subset operation.

For every measurement point i.e. every h, the total percentage of instances for three subsets is 100%. The 100% of y-axis applies separately for each translation direction. For example, for a given h, if we have 100 beamforming instances, and among these instances we have 90 instances where sub-array 2 is operational, 8 instances where sub-array 3 is operational, 2 instances for sub-array 1, then the percentage of sub-arrays 1, 2 and 3 are 2%, 90% and 8% respectively.

1. Test 1 results at 45 cm distance

Figure 6– Percentage of subset operation at d = 45 cm

2. Test 2 results at 90 cm distance

Figure 7– Percentage of subset operation at d = 90 cm

Figure 6 and Figure 7 presents the results of the mitigation test when the user is holding the EUT horizontally on his lap and is placed at a distance of 45 cm and 90 cm from the Docking Station (lid open at 110°). For h going from 0 cm to 20 cm subset 3 is 100% operational among the three subsets. The transition region is not observed in this test case since the subset 3 is 100% operational for all heights.

This shows that that the beam steering algorithm behaves in such a manner as to direct the energy away from the body by selecting only subset 3.

Note: In this EUT position, subset 3 is operational almost all the time rather than subset 1. This is related to a better link budget between the RFEM 3 and the dock station established by subset 3 in this EUT position. Indeed, from a side the dock station antennas are vertically polarized, and from the other side subset 3 is composed by eleven vertically polarized elements while subset 1 contain only four vertically polarized elements. That’s why subset 3 is active not subset 1. Therefore a scenario where subset 1 could be active is when the EUT is rotated of 90 degrees (the EUT screen become in portrait mode). In this case, the subset 1 polarization ensure better link budget than subset 3. In all cases the energy will be directed away from body.

3.7.2 Case 2: EUT placed horizontally with a lateral shifting to the side of the Lap, Lid open at 110°

Figure 8 and Figure 9 show the test results of the subset operation according to the EUT to lap distance (h), for the two horizontal distances: 45 and 90 cm respectively. The EUT is placed horizontally with a lateral shifting to the side of the Lap with the Lid open at 110°.

The x-axis represents the height above lap while the y-axis represents, for each subset, the percentage of subset operation.

1. Test 1 results at 45 cm distance

Figure 8– Percentage of subset operation at d = 45 cm

2. Test 2 results at 90 cm distance

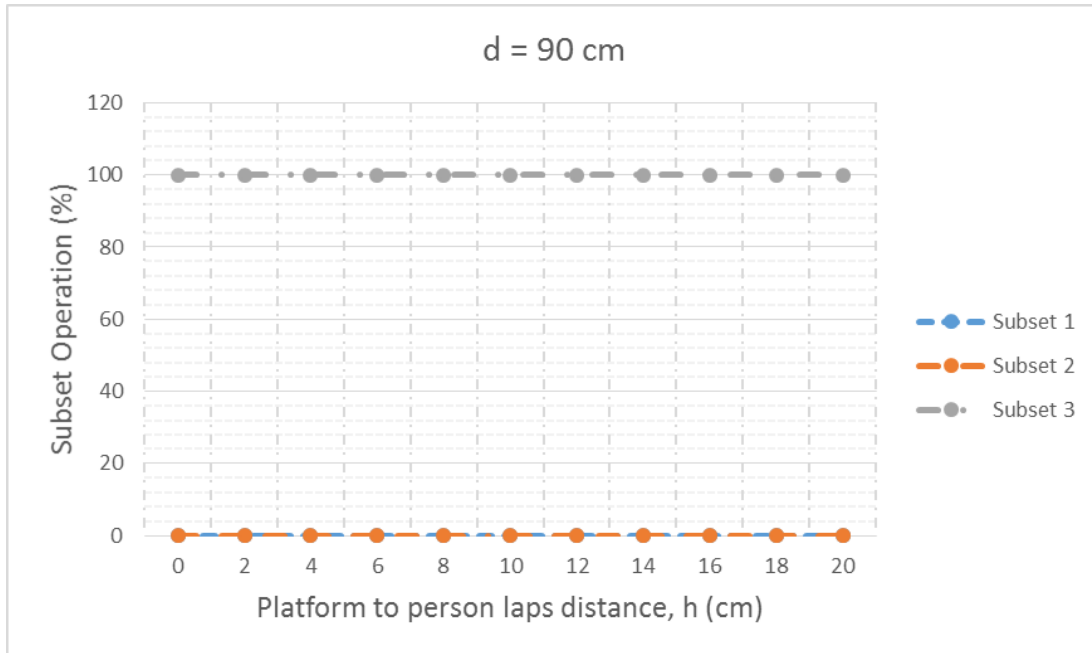

Figure 9– Percentage of subset operation at d=90 cm

Figure 8 and Figure 9 show the results of the mitigation test when the user is holding the EUT with a lateral shifting to the side of his Lap and is placed at a distance of 45 cm and 90 cm from the Docking Station (lid open at 110°). For h going from 0 cm to 20 cm subset 3 is 100% operational among the three subsets. The transition region is not observed in this test case since the subset 3 is 100% operational for all heights.

This shows that that the beam steering algorithm behaves in such a manner as to direct the energy away from the body by selecting only subset 3.

Note: In this EUT position, subset 3 is operational almost all the time rather than subset 1. This is related to a better link budget between the RFEM 3 and the dock station established by subset 3 in this EUT position. Indeed, from a side the dock station antennas are vertically polarized, and from the other side subset 3 is composed by eleven vertically polarized elements while subset 1 contain only four vertically polarized elements. That’s why subset 3 is active not subset 1. Therefore a scenario where subset 1 could be active is when the EUT is rotated of 90 degrees (the EUT screen become in portrait mode). In this case, the subset 1 polarization ensure better link budget than subset 3. In all cases the energy will be directed away from body.

3.7.3 Case 3: EUT placed horizontally on lap, Lid open at 160°

Figure 10 and Figure 11 show the test results of the subset operation according to the EUT to lap distance (h), for the two horizontal distances: 45 and 90 cm respectively when the Lid is open at 160°. The x-axis represents the height above lap while the y-axis represents, for each subset, the percentage of subset operation.

1. Test 1 results at 45 cm distance

Figure 10– Percentage of subset operation at d = 45 cm

2. Test 2 results at 90 cm distance

Figure 11– Percentage of subset operation at d = 90 cm

Figure 10 and Figure 11 present the results of the mitigation test when the user is holding the EUT horizontally on his lap and is placed at a distance of 45 cm and 90 cm from the Docking Station (lid open at 160°). For h going from 0 cm to 20 cm subset 3 is 100% operational among the three subsets. The transition region is not observed in this test case since the subset 3 is 100% operational for all heights.

This shows that that the beam steering algorithm behaves in such a manner as to direct the energy away from the body by selecting only subset 3.

Note: In this EUT position, subset 3 is operational almost all the time rather than subset 1. This is related to a better link budget between the RFEM 3 and the dock station established by subset 3 in this EUT position. Indeed, from a side the dock station antennas are vertically polarized, and from the other side subset 3 is composed by eleven vertically polarized elements while subset 1 contain only four vertically polarized elements. That’s why subset 3 is active not subset 1. Therefore a scenario where subset 1 could be active is when the EUT is rotated of 90 degrees (the EUT screen become in portrait mode). In this case, the subset 1 polarization ensure better link budget than subset 3. In all cases the energy will be directed away from body.

3.7.4 Case 4: EUT placed horizontally with a lateral shifting to the side of the Lap, Lid open at 160°

Figure 12 and Figure 13 show the test results of the subset operation according to the EUT to lap distance (h), for the two horizontal distances: 45 and 90 cm respectively. The x-axis represents the height above lap while the y-axis represents, for each subset, the percentage of subset operation.

1. Test 1 results at 45 cm distance

Figure 12– Percentage of subset operation at d=45 cm

2. Test 2 results at 90 cm distance

Figure 13– Percentage of subset operation at d=90 cm

Figure 12 and Figure 13 presents the results of the mitigation test when the user is holding the EUT with a lateral shifting to the side of his Lap and is placed at a distance of 45 cm and 90 cm from the Docking Station (lid open at 160°). For h going from 0 cm to 20 cm subset 3 is 100% operational among the three subsets. The transition region is not observed in this test case since the subset 3 is 100% operational for all heights.

This shows that that the beam steering algorithm behaves in such a manner as to direct the energy away from the body by selecting only subset 3.

Note: In this EUT position, subset 3 is operational almost all the time rather than subset 1. This is related to a better link budget between the RFEM 3 and the dock station established by subset 3 in this EUT position. Indeed, from a side the dock station antennas are vertically polarized, and from the other side subset 3 is composed by eleven vertically polarized elements while subset 1 contain only four vertically polarized elements. That's why subset 3 is active not subset 1. Therefore a scenario where subset 1 could be active is when the EUT is rotated of 90 degrees (the EUT screen become in portrait mode). In this case, the subset 1 polarization ensure better link budget than subset 3. In all cases the energy will be directed away from body.

3.8 Conclusion

For all the measured cases when the EUT is placed horizontally on lap, with and without transverse shifting, the test results presented in section 3.7.2 show that, at each horizontal distance and for all measured heights:

- Subset 3 with its beam directed away from the body, is operational almost all the time.

These test results confirm that the beam steering algorithm behaves in such a manner as to direct the energy away from the body while maintaining a good link budget.

Appendix A: Supplemental Numerical Modeling for RF Exposure Power Density Evaluation

A.1 Platform Simulation Methodology

A.1.1 Assessment considerations

During the system operation mode, it is challenging to define a practical system worst-case scenario in which the user is exposed to the highest emission level. To ensure coverage of the highest emission, the analysis of the worst-case condition is used and is emphasized in the following:

1. Platform orientation with respect to human body – In most of the cases, when the platform is very close to the human body, and the energy is directed to the human body, the human body will attenuate the signal. In this case, a reliable link can't be achieved. When a reliable link can't be maintained, the system enters search mode. In search mode, the system will transmit a low-duty cycle of less than 1%. This search mode contains signals which happen every 100ms at the maximum output power. However, in the analysis done for this document, the system is simulated in operational mode (not in search mode), operating at 70% duty cycle, which is much higher than the search mode.
2. Energy direction, beam forming – In order to avoid human body attenuation or object blockage of a reliable link, the system beam forming will automatically search for a path that will establish a more reliable link. So, in real life, in most of the cases the EM path will not be directed towards the human body (see Section 3). However, in the analysis presented in this document, worst-case beam forming direction is used.

Please note that the above worst-case assessment description is very conservative in that it is very unlikely that this case would happen under normal usage conditions. Since we cannot state with 100% certainty that this is impossible, we kept this worst-case assessment methodology for supplemental purposes. We ask that this be taken into consideration.

A.1.2 Near field and transition-zone field results

Finding the worst-case emission in the near field across the platform boundary requires searching on two orthogonal domains. One domain is the location – the need to find the place that has the worst-case energy. The other domain that has to be searched is the range of antenna phases – the need to search over the various antenna phases and find the antenna phase combination that gives the worst-case value. Section A.1.4 explains how these two worst-case (location and phase) searches are investigated.

After the completion of the worst-case phase analysis, the phases found during this analysis are used to find the worst-case spatially averaged power density across a 1cm^2 , for RF exposure evaluation purposes. EM simulation is used for this analysis.

Near-field analysis is simulated and correlated against measured lab results.

A.1.3 Simulation tool

A.1.3.1 Tool description

For the EM simulation, the commercially-available ANSYS Electronics Desktop 2016 (HFSS) is used. The ANSYS HFSS tool is used in the industry for simulating 3D, full-wave electromagnetic fields. Intel uses this EM simulation tool due to its gold-standard accuracy, advanced solver, and high-performance computing technology capabilities for doing accurate and rapid design of high-frequency components.

A.1.3.2 Solver description

The HFSS simulation is performed using the Finite Element Method, which operates in the frequency domain. The HFSS is based on an accurate direct solver with first order basis functions.

A.1.3.3 Convergence criteria and power density calculations

The HFSS uses a volume air box containing the simulated area to calculate the EM fields. The box is truncated by a Perfect Match Layer (PML) boundary condition. The simulation uses the adaptive mesh technique (see Figure 14) meet the exit criteria of $\Delta S < 0.02$. The ΔS is the change in the magnitude of the S-parameters between two consecutive passes; if the magnitude and phase of all S-parameters change by an amount less than the Maximum-Delta-S-per-Pass value from one iteration to the next, the adaptive analysis stops.

Figure 14 – Illustration of the adaptive mesh technique

After having the simulated electrical and magnetic (E and H) fields. The spatially averaged power density on a given surface is calculated as the surface integral of the Poynting vector:

$$W = \frac{1}{2} \text{Re} \int_S (\vec{E} \times \vec{H}^*) \cdot \vec{n} dS$$

Notes:

1. HFSS phasors in the field calculator are peak phasors, which leads to the $\frac{1}{2}$ factor in the Poynting vector calculation.
2. Figure 14 is an illustration of the adaptive mesh technique and is presented in the context of simulation methodology presentation.

A.1.4 Finding the near-field, worst-case simulation configuration

As explained previously, near-field analysis requires finding the worst-case location (along the searched plane) and antenna phase values. As further explained, the search should be done on two domains:

- 1) Look for the worst-case position (across the search plane).
- 2) Look for the two worst-cases antenna phases.

Note: The search plans are defined as the plans used for the calculation of the two worst-cases antenna phase combinations. The new RFEM 3 antenna is intended to operate according to one of three predefined subsets². For each subset an evaluation plane is defined taking into account the radiation direction of this subset. As The platform Dell P73G is used exclusively in laptop mode, for all subsets, the evaluation plane corresponds to the laptop base exposure plane.

Figure 15 – The x-z search on the base evaluation plane

Note that for the xyz coordinate references used throughout this report, we always consider the z-axis as being towards the body direction. This consideration is used to conserve a general consistency for the field's representation and calculations in the worst-case determination procedure detailed below. In summary, the xy plane is the evaluation plane, and the z-axis is the vector in propagation direction towards the body.

² A subset is a group of radiating elements which are excited simultaneously with the same amplitude. In RFEM 3, the number of subsets is three.

A.1.4.1 Terminology

- Element – Each one of the radiating elements that are used in the system. We denote the antenna element with index **k** in this explanation.
- N – Number of chains (RFEM 3 includes 24 radiated antenna elements – **N**=24). As described in the previous section, there are three subsets in RFEM 3. These subsets, named subset 1, subset 2 and subset 3, are composed of 10, 11 and 11 active elements respectively. For each subset, a set of elements from the 24 radiating antennas is activated).
- Point – Each point on the grid that is used for searching for the worst- case position. They are spaced 0.1mm from each other. The grid point would be denoted as **g** in this explanation.
- Complex E field vector generated by the kth antenna element at point g:

$$\vec{E}_{k,g} = \hat{x}(\text{Re}[E_{kx,g}] + j\text{Im}[E_{kx,g}]) + \hat{y}(\text{Re}[E_{ky,g}] + j\text{Im}[E_{ky,g}]) + \hat{z}(\text{Re}[E_{kz,g}] + j\text{Im}[E_{kz,g}])$$
- Complex H field vector generated by the kth antenna element at point g:

$$\vec{H}_{k,g} = \hat{x}(\text{Re}[H_{kx,g}] + j\text{Im}[H_{kx,g}]) + \hat{y}(\text{Re}[H_{ky,g}] + j\text{Im}[H_{ky,g}]) + \hat{z}(\text{Re}[H_{kz,g}] + j\text{Im}[H_{kz,g}])$$
- \hat{x} , \hat{y} , \hat{z} – unit direction vectors having unit magnitude and mutually orthogonal to each other.
- Without loss of generality in this explanation, RFEM 3 and the search plane are in the \hat{x} , \hat{y} plane, and the integrated 1cm² plane is perpendicular to direction \hat{z} .

Figure 16 – Near field worst-case terminology and orientation

A.1.4.2 Primer on field vector representation

For each subset, *E* and *H* fields generated by the k chain are

$$\vec{E}_k = \hat{x}(\text{Re}[E_{kx}] + j\text{Im}[E_{kx}]) + \hat{y}(\text{Re}[E_{ky}] + j\text{Im}[E_{ky}]) + \hat{z}(\text{Re}[E_{kz}] + j\text{Im}[E_{kz}])$$

$$\vec{H}_k = \hat{x}(\text{Re}[H_{kx}] + j\text{Im}[H_{kx}]) + \hat{y}(\text{Re}[H_{ky}] + j\text{Im}[H_{ky}]) + \hat{z}(\text{Re}[H_{kz}] + j\text{Im}[H_{kz}])$$

For each subset, *E* and *H* fields generated by all *N* chains (only subset elements are activated) are

$$\begin{aligned}\vec{E}_{\text{All}} &= \vec{x} \sum_{k=1}^N (\text{Re}[E_{kx}] + j\text{Im}[E_{kx}]) + \vec{y} \sum_{k=1}^N (\text{Re}[E_{ky}] + j\text{Im}[E_{ky}]) + \vec{z} \sum_{k=1}^N (\text{Re}[E_{kz}] + j\text{Im}[E_{kz}]) \\ \vec{H}_{\text{All}} &= \vec{x} \sum_{k=1}^N (\text{Re}[H_{kx}] + j\text{Im}[H_{kx}]) + \vec{y} \sum_{k=1}^N (\text{Re}[H_{ky}] + j\text{Im}[H_{ky}]) + \vec{z} \sum_{k=1}^N (\text{Re}[H_{kz}] + j\text{Im}[H_{kz}])\end{aligned}$$

The Poynting vector generated by all N chains is

$$\begin{aligned}\vec{P}_{\text{General,All}} &= \frac{1}{2} \vec{E}_{\text{All}} \times \vec{H}_{\text{All}}^* \\ &= \frac{1}{2} \left\{ \vec{x} \left\{ \sum_{k=1}^N (\text{Re}[E_{ky}] + j\text{Im}[E_{ky}]) \sum_{k=1}^N (\text{Re}[H_{kz}] - j\text{Im}[H_{kz}]) \right. \right. \\ &\quad \left. \left. - \sum_{k=1}^N (\text{Re}[E_{kz}] + j\text{Im}[E_{kz}]) \sum_{k=1}^N (\text{Re}[H_{ky}] - j\text{Im}[H_{ky}]) \right\} \right. \\ &\quad \left. + \vec{y} \left\{ \sum_{k=1}^N (\text{Re}[E_{kz}] + j\text{Im}[E_{kz}]) \sum_{k=1}^N (\text{Re}[H_{kx}] - j\text{Im}[H_{kx}]) \right. \right. \\ &\quad \left. \left. - \sum_{k=1}^N (\text{Re}[E_{kx}] + j\text{Im}[E_{kx}]) \sum_{k=1}^N (\text{Re}[H_{kz}] - j\text{Im}[H_{kz}]) \right\} \right. \\ &\quad \left. + \vec{z} \left\{ \sum_{k=1}^N (\text{Re}[E_{kx}] + j\text{Im}[E_{kx}]) \sum_{k=1}^N (\text{Re}[H_{ky}] - j\text{Im}[H_{ky}]) \right. \right. \\ &\quad \left. \left. - \sum_{k=1}^N (\text{Re}[E_{ky}] + j\text{Im}[E_{ky}]) \sum_{k=1}^N (\text{Re}[H_{kx}] - j\text{Im}[H_{kx}]) \right\} \right\}\end{aligned}$$

Power flow is

$$\begin{aligned}\text{Re}[\vec{P}_{\text{General,All}}] &= \frac{1}{2} \left\{ \vec{x} \left\{ \sum_{k=1}^N \text{Re}[E_{ky}] \sum_{k=1}^N \text{Re}[H_{kz}] + \sum_{k=1}^N \text{Im}[E_{ky}] \sum_{k=1}^N \text{Im}[H_{kz}] - \sum_{k=1}^N \text{Re}[E_{kz}] \sum_{k=1}^N \text{Re}[H_{ky}] \right. \right. \\ &\quad \left. \left. - \sum_{k=1}^N \text{Im}[E_{kz}] \sum_{k=1}^N \text{Im}[H_{ky}] \right\} \right. \\ &\quad \left. + \vec{y} \left\{ \sum_{k=1}^N \text{Re}[E_{kz}] \sum_{k=1}^N \text{Re}[H_{kx}] + \sum_{k=1}^N \text{Im}[E_{kz}] \sum_{k=1}^N \text{Im}[H_{kx}] - \sum_{k=1}^N \text{Re}[E_{kx}] \sum_{k=1}^N \text{Re}[H_{kz}] \right. \right. \\ &\quad \left. \left. - \sum_{k=1}^N \text{Im}[E_{kx}] \sum_{k=1}^N \text{Im}[H_{kz}] \right\} \right. \\ &\quad \left. + \vec{z} \left\{ \sum_{k=1}^N \text{Re}[E_{kx}] \sum_{k=1}^N \text{Re}[H_{ky}] + \sum_{k=1}^N \text{Im}[E_{kx}] \sum_{k=1}^N \text{Im}[H_{ky}] - \sum_{k=1}^N \text{Re}[E_{ky}] \sum_{k=1}^N \text{Re}[H_{kx}] \right. \right. \\ &\quad \left. \left. - \sum_{k=1}^N \text{Im}[E_{ky}] \sum_{k=1}^N \text{Im}[H_{kx}] \right\} \right\}\end{aligned}$$

A.1.4.3 Domain search for worst-case direction

The two domain search is completed (for each subset) as follows:

- A. First find a direction (location) for the worst-case 1cm² square averaging area using upper-bound methods.

The basic concept behind the upper-bound method is to assume that there could be an “ideal beam forming” mechanism that could align the phases of all the elements for both E and H fields. (Obviously, in real life this cannot happen. This is the reason that this is an upper-bound method). When this ideal mechanism is used, then all the complex phasors are aligned to the same phase, hence the phasor absolute value can be used instead of the phasor. The E (and H) field for any direction is the sum of the magnitude of the fields (look at item 3, below, for a more formal description).

This method provides the worst-case position independent of the antenna phases. It allows finding the worst-case location with this “ideal beam forming” mechanism.

Item 3, below, translates the above verbal description into more formal mathematical wording.

- B. After the worst-case direction is found using the upper-bound method for each subset, the antenna phases are aligned to this direction. The antenna phases are aligned to maximize the power across the 1cm² averaging area that was found using the upper-bound method. The method that is used to find the required antenna phases is as follows: first order the antennas of the subset according to the power contribution on the found 1cm² from the highest to the lowest. Then start by activating the antenna that contributes the most, set its phase to 0, and then activate the 2nd antenna and search over the phases for the 2nd antenna. Choose the phase that maximizes the power of the two antenna elements. To find the phase for the third antenna, fix antenna 1’s phase to zero and antenna 2’s phase to the value that was found before. Then search for the phases for the third antenna that maximize the power. Continue with the same process until you reach the last subset element. The same process is used to find the second worst case.
- C. Calculate the power density with the antenna phases that were found in the previous item (item B).

The above process can be written as the following algorithm:

1. A grid is defined with 0.1mm spacing.
2. At each point in the grid, the complex E and H fields are calculated using each one of all radiating elements in the involved subset, separately. Each one of the calculated E and H fields are 3D complex vectors, so the simulation output from this stage is 10, 11, 11 3D complex E field strength vectors and 10, 11, 11 3D complex H field strength vectors for the three subsets respectively . The vectors are defined as:

$$\begin{aligned}\vec{E}_{k,g} &= \vec{x}(\text{Re}[E_{kx,g}] + j\text{Im}[E_{kx,g}]) + \vec{y}(\text{Re}[E_{ky,g}] + j\text{Im}[E_{ky,g}]) + \vec{z}(\text{Re}[E_{kz,g}] + j\text{Im}[E_{kz,g}]) \text{ and} \\ \vec{H}_{k,g} &= \vec{x}(\text{Re}[H_{kx,g}] + j\text{Im}[H_{kx,g}]) + \vec{y}(\text{Re}[H_{ky,g}] + j\text{Im}[H_{ky,g}]) + \vec{z}(\text{Re}[H_{kz,g}] + j\text{Im}[H_{kz,g}])\end{aligned}$$

3. Upper-bound assumption is used to derive the E and H field on each one of the grid points. The following items describe the upper-bound method that is used:
 - a. The calculation is made separately for E field and H field.

- b. For E field, the following calculation is made independently for each one of the grid points:

$$\begin{aligned} \vec{E}_{UB,g} = \hat{x} \sum_{k=1}^N \sqrt{\text{Re}[E_{kx,g}]^2 + \text{Im}[E_{kx,g}]^2} + \hat{y} \sum_{k=1}^N \sqrt{\text{Re}[E_{ky,g}]^2 + \text{Im}[E_{ky,g}]^2} \\ + \hat{z} \sum_{k=1}^N \sqrt{\text{Re}[E_{kz,g}]^2 + \text{Im}[E_{kz,g}]^2} = \hat{x} \sum_{k=1}^N |E_{kx,g}| + \hat{y} \sum_{k=1}^N |E_{ky,g}| + \hat{z} \sum_{k=1}^N |E_{kz,g}| \end{aligned}$$

The magnitude of the complex E vector is summed over the antenna elements in a subset. The summation is done for each one of the grid points, and for each one of the elements in each direction, independently.

- c. The output of the previous item is the 3D real vector of the E field on each one of the simulated grid points in each direction. The physical implementation is that an ideal beam forming was done for the E field for each one of the points.
- d. The same process as described in item b is done for the H field.

$$\begin{aligned} \vec{H}_{UB,g} = \hat{x} \sum_{k=1}^N \sqrt{\text{Re}[H_{kx,g}]^2 + \text{Im}[H_{kx,g}]^2} + \hat{y} \sum_{k=1}^N \sqrt{\text{Re}[H_{ky,g}]^2 + \text{Im}[H_{ky,g}]^2} \\ + \hat{z} \sum_{k=1}^N \sqrt{\text{Re}[H_{kz,g}]^2 + \text{Im}[H_{kz,g}]^2} = \hat{x} \sum_{k=1}^N |H_{kx,g}| + \hat{y} \sum_{k=1}^N |H_{ky,g}| + \hat{z} \sum_{k=1}^N |H_{kz,g}| \end{aligned}$$

- e. At each point in the grid, the Poynting vector is calculated by vector multiplication of the E and H fields, which are added up in items b and d. As explained before, without a loss of generality, we assume that the search plane is the x/y plane. All three (xyz) components of the Poynting vector are added, and not just the component that is normal to the x/y plane:

$$\begin{aligned} P_g = \frac{1}{2} \text{Re}\{(\vec{E} \times \vec{H}^*)\} &= \frac{1}{2} \text{Re}\{((E_y H_z^* - E_z H_y^*)) \hat{x} + ((E_z H_x^* - E_x H_z^*)) \hat{y} + (E_x H_y^* - E_y H_x^*) \hat{z}\} \\ P_{g,x} &= \frac{1}{2} \text{Re}\{E_y H_z^* - E_z H_y^*\} \\ P_{g,y} &= \frac{1}{2} \text{Re}\{(E_z H_x^* - E_x H_z^*)\} \\ P_{g,z} &= \frac{1}{2} \text{Re}\{E_x H_y^* - E_y H_x^*\} \\ P_{UpperBound_g} &= \sqrt{P_{g,x}^2 + P_{g,y}^2 + P_{g,z}^2} \end{aligned}$$

4. The above calculated Poynting vectors are used to estimate the power across 1cm² area.

$$P_{1cm^2} = \iint_{1cm^2} P_{UpperBound_g \ x,y,z}$$

5. The 1cm² area with the highest power value is used as the worst-case direction of a subset. The antenna phases are aligned to maximize the energy in this 1cm² area, as explained below in order to find the 2 worst cases:

- a. Turn on each element one-by-one to find order of power intensity in the 1cm^2 window. (Find the order of contribution)
 - b. Sort in the power order from the highest to the lowest, #0 to #(10, 11, 11) for the involved subsets 1,2 and 3 respectively .
 - c. Turn on #0 with phase $P_0=0$. (reference)
 - d. Turn on #1 and change the phase to maximize the power and find the phase P_1 .
 - e. Keep P_0 and P_1 on, then turn on #2 and do same.
 - f. Repeat for the rest of the antennas.
6. Using the antenna phases that were calculated in step 5, the power density is calculated along the evaluation plane and then spatially averaged across a 1cm^2 area.

A.1.5 3D models used in the simulation

A.1.5.1 Worst-case operating conditions of the platform

The platform Dell P73G is a platform with the ability to be used exclusively in laptop mode, the worst case exposition to the radio frequency radiation can happen when the body of the user is in contact with the platform. The evaluation plane (blue area) shown the Figure 17 represent the worst case contact plane from the platform to the body.

Figure 17 – Worst-case evaluation plane for Dell model P73G platform

A.1.5.2 RFEM 3 housing inside Intel 18265NGW module

The 3D Intel 18265NGW module is simulated inside the Dell P73G platform. Figure 18 shows the position of the RFEM 3 antenna, which is located inside the lid at the bottom right the screen.

Figure 18 – Platform picture with RFEM 3 location

A.1.5.3 Closest distance to the body of an end user

In operating mode, the human body is below the base (keyboard). This mode represents the case in which a person holds the platform their legs. In this scenario the worst case emission is searched along the base plane showed in Figure 17.

In this case, the human body is below the Laptop – this mode represents the case in which a person places the Laptop on their lap. In this scenario, the worst case emission is searched along the base evaluation plane (showed in blue in Figure 17) and the distance between human body to the active antenna is 2 mm.

Figure 19 shows a cross-section (in the yz-plane) of the platform with the RFEM 3 inside the platform.

Figure 19 – Platform plans touching the body

A.1.5.4 Metals in proximity of the RFEM 3

All the metals that are in the RFEM 3 region (13.35 mm on each side) were included in the simulation.

A.1.6 Antenna feed

This section provides a general description of the numerical simulations; other details of the simulation geometry are included in reference [1]. The EM simulation uses an accurate 3D model of the RFEM 3 antenna. The model includes the antenna elements as well as their feeding lines.

In the simulation (as well as in the product), each antenna element is fed independently, and we excite the antennas at the origin of the antenna structure on the RFEM 3. (The antenna structure includes the silicon chip, the solder bumps, the vias, traces and actual antenna element.)

As described previously, the RFEM 3 antenna will be operated according to one of three predefined subsets. For the operational subset, signals of equal amplitude are applied to the feed-points of individual array elements, and the aggregate equivalent conducted power to all array elements corresponds to the sum of all elements' powers. In the worst-case power density the subset 1 is the operational subset with an equivalent conducted power of 5.5 dBm; thus each element is fed by -4.5 dBm (5.5 dBm divided over ten elements).

The total power (same per element) is used to build the pattern of radiated power through beam forming. For building the beam forming pattern, the same power is used per element, while phase is changed per element. (Refer to Section 2.2 for more information about beam forming). Phases are derived for each excitation separately, to simulate the worst-case condition. Section A.1.4 explains how the phases are derived to find the worst case condition.

A.2 Power Density Simulation Results

A.2.1 Introduction

The evaluation plans presented in Section A.1.5.2 has been simulated according to the methodology described in Section A.1. The simulation results for all subsets in the concerned evaluation plans are presented in this section.

The power density has been simulated over three channels with frequencies listed in Table 4. For each channel, we'll present the resulting details according to the methodology explained in Section A.1.4:

- Simulation results of the upper bound single-point power density for each single-point across the mesh ($P_{UpperBound_g}$). Please note that this value represents single-point power density and not spatially averaged power density over 1cm^2 . Even though a $1\text{mW}/\text{cm}^2$ scale is used, this value represents an upper-bound power density for each single point of the mesh, which is a much smaller area than 1cm^2 .
- The results of the single-point power density using the antenna phases corresponding to the first and second worst-cases.
- Spatially averaged power density over 1cm^2 results of the first and second worst-case for each subset antenna phases. These results present the spatially averaged power density across 1cm^2 using the xyz components of the Poynting vector.
- All results for all channels and subsets are normalized to the target maximum power of 5.5 dBm

Table 4 – WiGig channel frequencies

	Channel 1	Channel 2	Channel 3
Frequency (GHz)	58.32	60.48	62.64

Table 5 summarizes all the simulation configurations as well as the result types presented in this section:

Table 5 – Power density simulation configuration and result details

			Worst-case distribution ⁽¹⁾	[3 plots] – Very worst case	Section A.2.6

⁽¹⁾ The distribution of the found worst case spatially averaged power density among the 18 calculated worst cases.

A.2.2 Upper bound power density values in the evaluation plane

The Upper Bound single-point power density is calculated for each subset of the antenna. Table 6 summarizes, for all subsets, the maximum calculated upper bound single point power density.

Please note that since the worst-case conditions are searched over a plane for near field, then the azimuth and the elevation are not relevant. The worst-case position is calculated using all the power density single-points issued from the upper-bound simulation results. We leverage the phase conditions for each antenna element that resulted in these worst-case conditions to evaluate final spatially averaged power density. The mathematical basis for using these as the worst-case phase conditions to evaluate the final spatially averaged power density were provided in Section A.1.4.3.

Table 6 – Maximum upper bound single point power density [mW/cm²]

	Channel 1	Channel 2	Channel 3
Subset 1	15.001	14.776	15.200
Subset 2	14.000	11.471	9.806
Subset 3	16.254	14.999	13.647

A.2.3 Worst-case antenna phases in the evaluation plane

The phase's configurations a.k.a. 'beamforming codes' for the first and second worst power density cases are calculated for each subset and each channel using the phase search algorithm detailed in bullet 5 of Section A.1.4.3.

Table 7 and Table 8 shows, for each channel, the phases of each subset elements (marked in grey) in the first and second worst power density case respectively. The white cells with phase ("-") correspond to the non-active elements of the subset. For instance, for subset 1, the active elements are 7, 8; 17 to 24 and the worst case occurs for each channel with the indicated phases. "Ph #" indicates the number of the attributed phase combination for each worst case.

Note: The final antenna phases worst cases, used later in measurement, corresponds to the four highest maximum spatially averaged power density values among the eighteen calculated worst cases (3 channels x 3 subsets x 2 first worst-cases) showed in Table 10.

Table 7 –Phases configurations for the first worst case for all antenna subsets

Antenna index	Subset 1 – Base plane Phases [Degrees]			Subset 2 –Base plane Phases [Degrees]			Subset 3 – Base plane Phases [Degrees]

A.2.4 Single-Point power density values in the evaluation plane

Table 9 presents, for all channels and subsets, the calculated single-point power density values in the concerned evaluation plane using the first and the second worst-case subset antenna phases presented in Table 7 and Table 8 respectively (18 Worst cases).

Table 9 – Maximum single point power density [mW/cm²]

	First worst case			Second worst case		
	Channel 1	Channel 2	Channel 3	Channel 1	Channel 2	Channel 3
Subset 1	2.600	2.340	1.964	1.562	1.653	1.485
Subset 2	1.099	1.455	1.251	1.164	1.394	1.411
Subset 3	1.652	1.838	1.442	1.793	1.453	1.709

A.2.5 Spatially averaged power density over 1 cm² values in the evaluation plane

Table 10 shows, for all channels and subsets, the calculated spatially averaged power density over 1 cm² at 100% duty cycle (Eighteen Calculated worst cases). These values are calculated in the concerned evaluation plane using the first and the second worst-case subset antenna phases shown in Table 7 and Table 8 respectively. The 6 highest spatially averaged power density are marked in bold in Table 11. Simulated field and power density distributions at the evaluation plane are provided for the six configurations in Section A.2.7.

Table 10 – Maximum spatially averaged power density over 1cm² [mW/cm²]

	First worst case			Second worst case		
	Channel 1	Channel 2	Channel 3	Channel 1	Channel 2	Channel 3
Subset 1	0.811	0.780	0.668	0.656	0.592	0.514
Subset 2	0.359	0.357	0.348	0.357	0.353	0.325
Subset 3	0.647	0.621	0.463	0.608	0.565	0.442

Table 10 shows that the very worst case is found for **subset 1 at channel 1** (marked in orange) with spatially averaged power density of **0.811mW/cm²** at 100 % duty cycle. The next section presents all power density distributions for this worst cases.

A.2.6 Worst case power density distribution

As described in the previous section, the worst case spatially averaged power density over 1 cm² among the eighteen calculated worst-cases is found for subset 1, channel 1. The worst case subset antenna phase's configuration used in this case is for the first worst case (see Table 7, subset 1 / channel 1 configuration).

This section present for this worst case the distribution of the following listed items:

- Upper bound single point power density distribution
- Single-point power density distribution
- One dimensional cut of the single-point power density distribution
- Spatially averaged power density over 1 cm²

A.2.6.1 Upper-bound power density distribution

Figure 20 presents upper-bound, single-point power density of subset 1, channel 1 which is the worst case among the two simulated worst cases of the three subsets. The evaluation plane of subset 1 is the base plane represented in Figure 17.

The footprint of the platform components in the base evaluation plane for single-point power density representation is shown in Figure 22.

Worst-case coordinates on channel 1 are X=-0.100 cm, Y=0.030 cm.

Figure 20 – Channel1 upper-bound, single-point power density- subset 1

A.2.6.2 Single point power density distribution

Figure 21 presents the single-point power density distribution of subset 1, channel 1 in the base plane using the worst-case antenna phases of subset 1 (see Table 7)

The footprint of the platform components in the base plane for single-point power density representation is shown in Figure 22.

Worst-case coordinates on channel 1 are $X=-0.2900$ cm, $Y=0.04000$ cm.

Figure 21 – Channel 1 single-point power density - subset 1

Figure 22 – Footprint of single-point power density plane representation

A.2.6.3 One dimensional cut of the single-point power density distribution

In Figure 23 and Figure 24, we present the simulation results from the xyz components of single-point power density values with worst-case antenna phases of subset 1, channel 1 which is the worst case among the three subsets. The figures represent a 1-dimensional cut in the x-axis and y-axis that shows the behavior of the near field power density at the evaluation plane.

Figure 23 – 1-dimensional plots of the power density along x dimension

Figure 24 – 1-dimensional plots of the power density along y dimension

A.2.6.4 Distribution of Spatially averaged power density over 1 cm²

Figure 25 presents the spatially averaged power over 1cm² at 100% duty cycle for the worst-case scenario of subset 1, channel 1 as explained in Section A.1.4.3.

The 1cm² square location correspondent to the maximum of spatially averaged power density value is plotted in Figure 25 for the channel 1.

Worst-case coordinates on channel 1 are X=-0.1300 cm, Y=0.13000 cm.

Figure 25 – Channel 1– spatially averaged power density over 1cm² - subset 1

The Table 11 shows the simulated worst-case power density, for subset 1 – channel 1, in the evaluation plane.

Table 11 – Worst-case power density – Subset 1

Highest power density	Subset 1 - Channel 1
70% duty cycle	0.567
100% duty cycle	0.811

Notes for Table 11

1. The worst-case power density is found for channel 1 on subset 1.
2. The Maximum power density (spatially averaged over worst 1cm²) in channel 1 is achieved at 0 mm distance from the platform boundary and equals 0.811mW/cm² over 100% duty cycle.
3. As explained in Section 2.4, the Intel 18265NGW module is limited to transmit at a duty cycle of 70% over 10 seconds. Therefore the maximum spatially-integrated and time-averaged power density over 1cm² is 0.811x 0.7 = 0.567 mW/cm².

A.2.7 Field and Power Density Distributions for the Six Highest Worst Cases

This section shows the E-field, H-field, local power density and spatially averaged power density distribution at the corresponding evaluation plane of the six highest worst cases spatially averaged power density determined in section A.3.5 and marked in bold in Table 11.

The table below list the identified highest six- spatially averaged power density worst cases

Table 12 – Highest six worst-case spatially averaged power density

	Subset	Channel	Worst-case	Simulated AVG. PD	Phase config	Plot
Worst-Case #1	1	1	1	0.811	Ph #1	Plot #1
Worst-Case #2	1	2	1	0.780	Ph #2	Plot #2
Worst-Case #3	1	3	1	0.668	Ph #3	Plot #3
Worst-Case #4	1	1	2	0.656	Ph #10	Plot #4
Worst-Case #5	3	1	1	0.647	Ph #7	Plot #5
Worst-Case #6	3	2	1	0.621	Ph #8	Plot #6

A.2.8 Conclusion

The simulation results for the three subsets in the concerned evaluation plane for three channels were presented in this report. The worst case is observed on channel 1 for subset 1, with the maximum total spatially averaged power density of 0.567 mW/cm^2 . Note that the applicable FCC limit is 1 mW/cm^2 .
