

Statement according to FCC part 15 section 15.407(c)

Base station MicroMax 5.6 GHz TDD Int

This 802.16d (WiMAX) equipment will transmit only when client equipment is authorized and connected to IP packet networks, which in nature do not transmit without a request. Therefore, the base station (BS) that operates as a bridge with TDMA scheduler and burst modulation will not pass any information to the radio when there is no specific client registered and only that information.

Subscriber (terminal) station, ProST 5.6 GHz TDD Int and EasyST 5.6 GHz TDD Int

Including the relevant base station (BS) nature of operation described above. The subscriber station (SS) will transmit only according to the BS order: limited to allocation in time, maximum duration predetermined inside the BS and according to IP traffic allowed connection. Therefore only information with outside IP network addressed will be transmitted. Because this is Point to Multipoint TDMA system, the BS will not allocate transmit time without request and the SS will not request without real need.

For the case of operational failure we are monitoring the client periodically, 5 sec, for proper operation. The BS/SS also monitor themselves.
