Configuration

WLAN Cable Access Point 6220 (APU, CSU) have a various features about a management and operation as listed below.

Software Installation

APU Basic Configuration and Operation Test

APU Basic Configuration and Operation Test

Testing the connection between APU and CSU

Testing Wireless Network Performance

Basic Configuration

Advanced and Optional Configuration

## Software Installation (AP Configurator)

The WLAN Cable AP Configurator is used to configure your wireless networking devices. Both the executable file needed to install the Configurator and the online help for the Configurator (*.chm) are included on the Software CD that you received with your hardware device. Refer to the online help or the WLAN Cable AP Configuration User Guide on the Document CD for detailed instructions on how to configure your device. This section explains the system configuration in detail..

Note: The features available to you in the WLAN Cable AP Configuration vary depending on the version of the software. This section explains all possible features involved in basic configuration. Your actual software may not display all of the features and fields described.

Installing the Configurator Software

1. Insert the Software CD into your PC's/laptop's CD ROM drive, then you can see the installation web page as below.

**Figure 4-1**
Software CD Starting Display
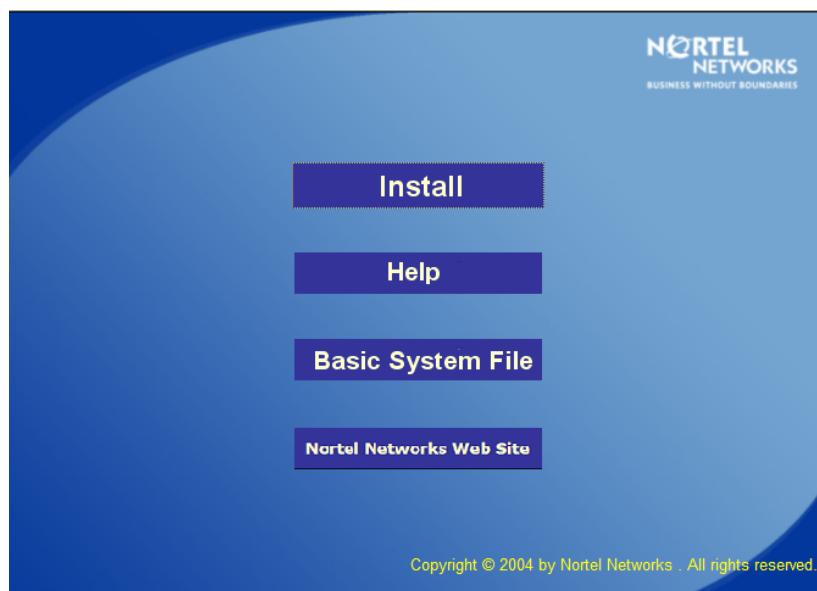

2. Click the installation button and press "open" button while finding the dialog box.
3. Double click the name of the Configurator Installation program (the .exe file on your Software CD).

Figure 4-2
Software Installation Launching
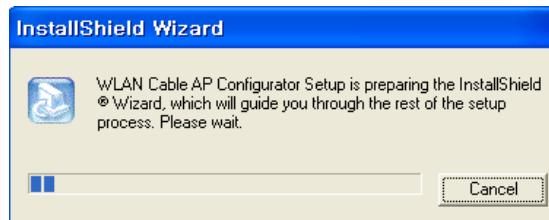

3. Follow the onscreen instructions to install the Configurator.

Figure 4-3
Installation Dialog Window
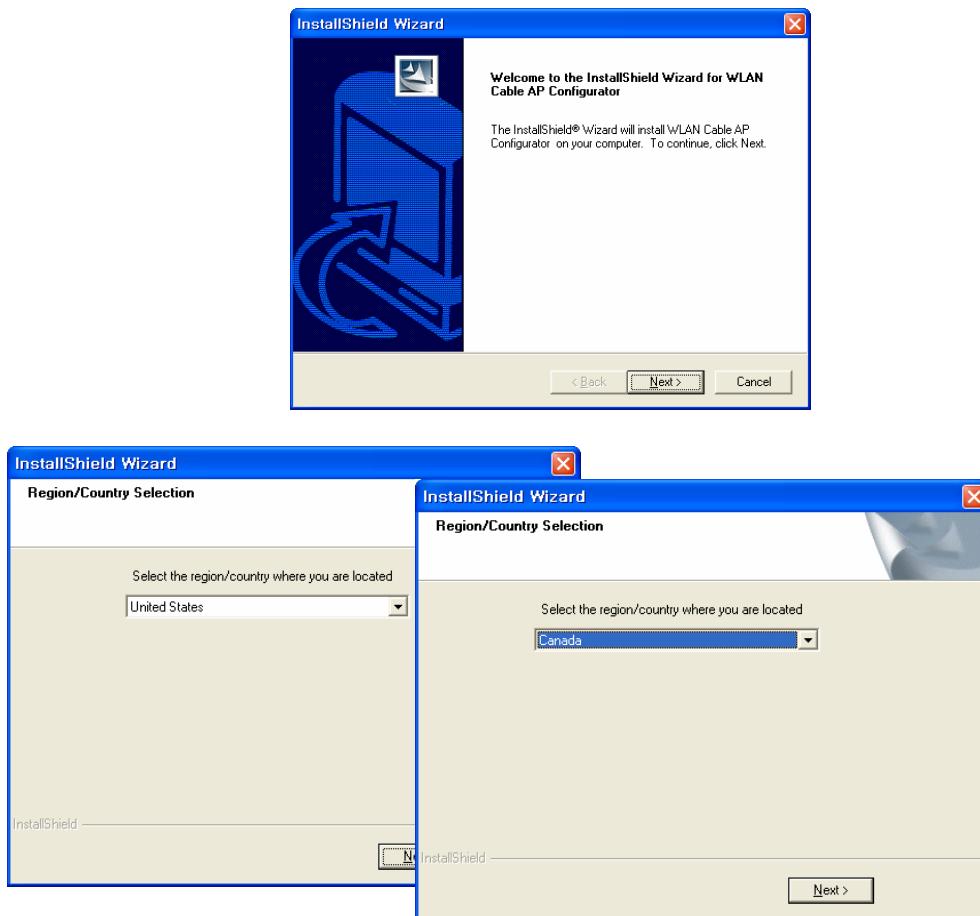

If you are installing the Configurator for the first time, files are stored in the directory Program Files/Nortel/WLAN Cable AP Configurator. If you are upgrading from a previous Configurator installation, your files will be stored in the directory where you last saved the Configurator files. The Install Shield also installs shortcuts to the Configurator on your desktop.

Procedure 3-1
**APU Basic configuration and Operation Test**

Action

Step	Action

1. Prepare a Laptop computer and a client unit to test and configure the APU at the installation field.
2. There are two kinds of test setup between APU and Wi-Fi Radio card as below.
    A. Type I (Radio Connection: Primary)
        This type of test setup is very simple and reliable to setup and test the operation of APU without additional accessories except PCMCIA type radio card.
        APU operation test can be performed with only a radio connection between the antenna of the APU and Wi-Fi Radio Card in Laptop PC as shown in Figure 4.4
    B. Type II (RF Cable Connection: Secondary)
        In case the more secure and reliable set, APU operation test can be performed with a RF cable between the antenna of the APU and Wi-Fi Radio Card in Laptop PC.
        This type of test setup may be a little cumbersome but, can check more securely APU operation and configuration excluded in any interference from a various radio devices around the site.
        Please make sure the cable has each different termination type at both ends (APU side: N type Male, Radio card side: PC card)
3. Be aware that the APU initially unpacked has the default parameter followed as below

Factory Default

- IP address: DHCP Client (Ethernet 1)
- Read Write Password: public
- SNMP Secure Configuration Password: public
- IEEE 802.11 Interface Setup
    - Mode Selection: 802.11 compatible Access Point Mode
    - Frequency: CH1 (2412 MHz)
    - Transmit Rate: 11Mbps
    - SSID: WLAN Cable AP
   - WEP Encryption: Disable

**Figure 4-4
Test Network Configuration (Radio Connection)**
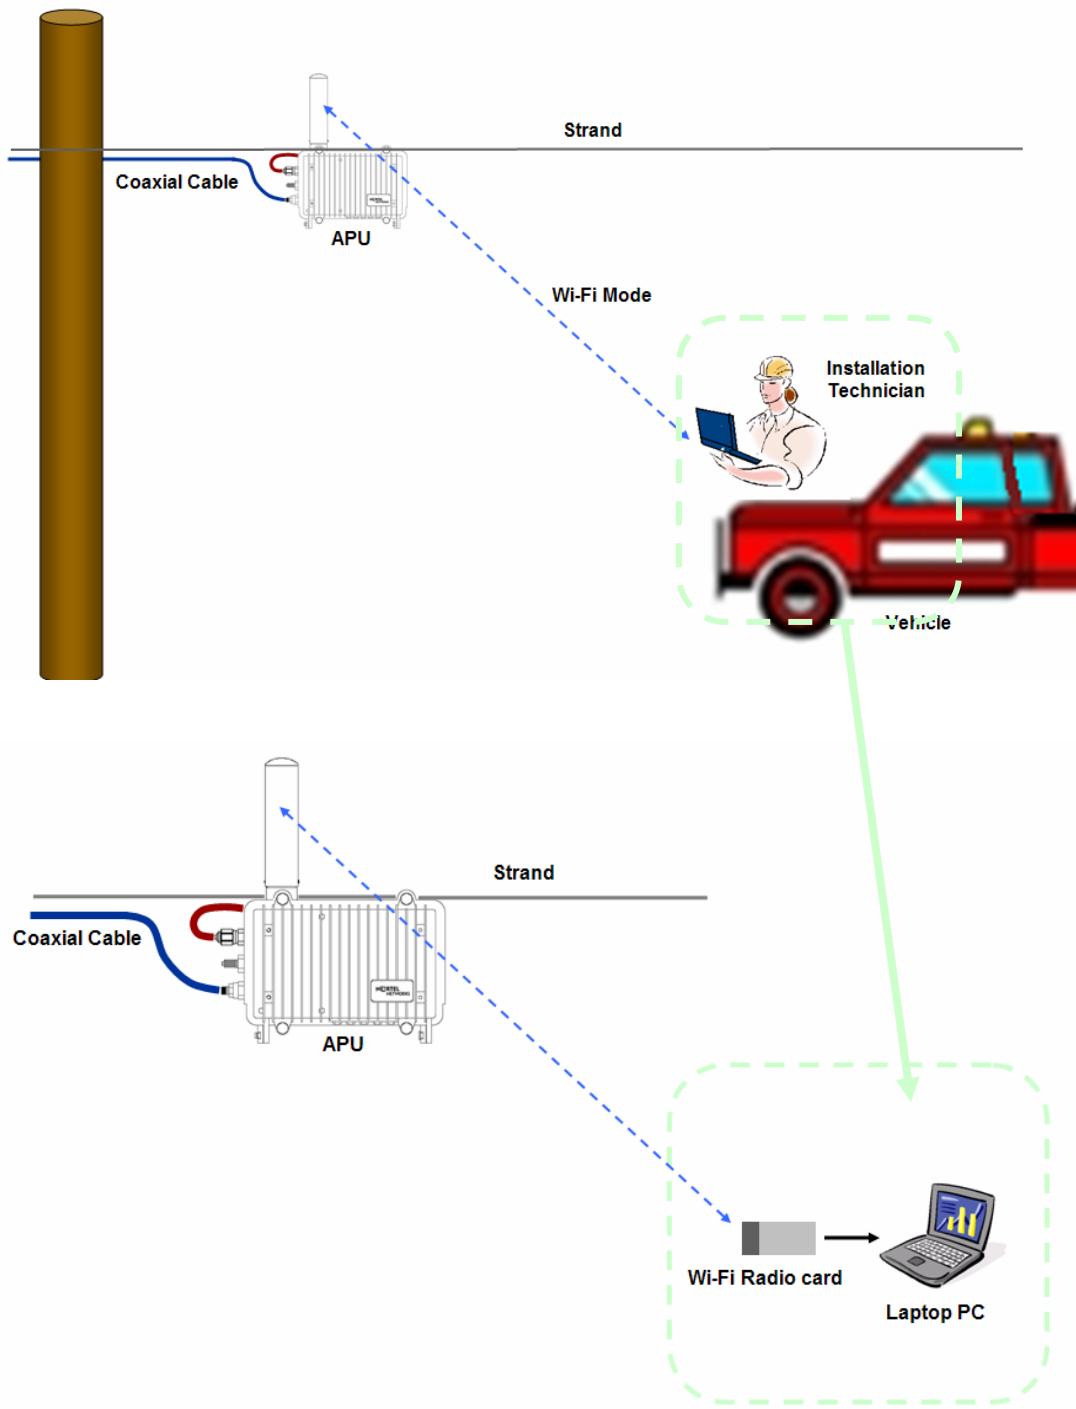

4. Search the APU by scanning it's default SSID "WLAN Cable AP" at a laptop computer and connect to the entity and then, check if the radio signal shows a good performance.

5. Launch the Configurator by either double clicking the WLAN Cable AP Configurator icon in your desktop or by opening the file config.exe from the directory "C:\Program Files\Nortel\WLAN Cable AP Configurator" where software is installed

6. The Configurator runs and the IP Address for your APU (and the IP addresses for any other devices in your network) appears in the Configurator window, as shown below.

**Figure 4-5**
Configurator Starting Window
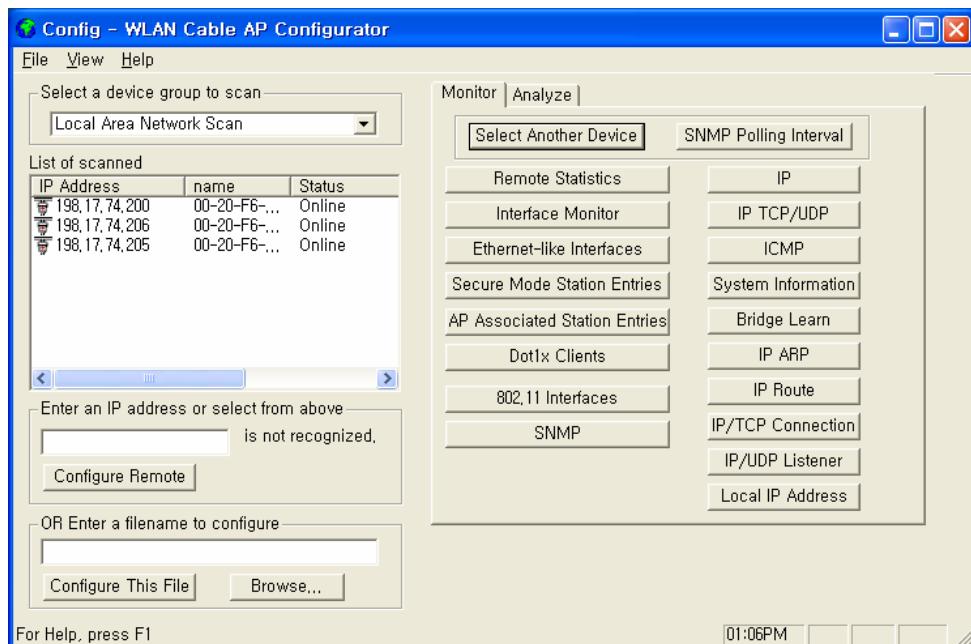

7. Make sure that the laptop computer gets an IP address from the DHCP server at Network Center by checking an IP address list box at the left side of the configurator window.

8. If the APU you wish to configure is on the same network subnet as your computer, you can select it from the list that is automatically displayed in the IP Address window. Press the<F5> key to refresh the scan list. Alternately, you can also right click anywhere in the scan window and select Re-scan local network.

Note: To differentiate the APU to be configured, you should check the AP MAC address of APU which is printed on the label attached on the side of APU.

9. If you can find out the IP address of APU on the IP address window, Move a mouse pointer on the IP address.

Figure 4-6
IP address list box
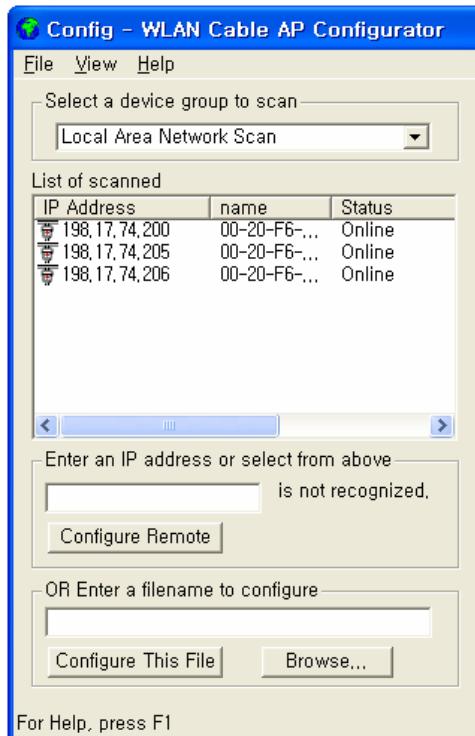

10. Right click on the IP address, and click the Configure button below
    the list box on the left side of a configurator window. The
    Read/Write Password screen is displayed, as shown below.

Figure 4-7
SNMP Password (Read/Write)

11. Enter the password "public" for the device you have selected at both
    text boxes, and then click the OK button.
12. If the Setup tab is displayed in the main window as shown below,
    SNMP checking is a success.

Figure 4-8
Setup Tab
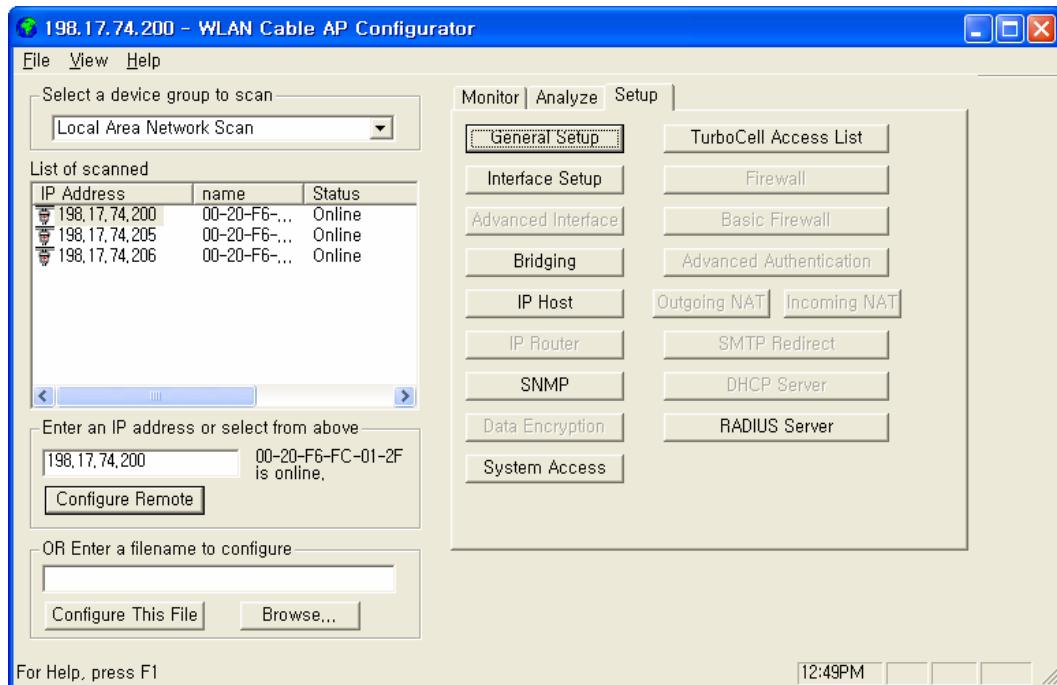

> **Note:** When you test the APU with Test CSU, you don't have to change the parameters of APU with AP configurator. But, after all test completed, you should configure APU according to your local network design idea.

13. Perform Ping Test to the specific IP address of network entity which is located at the public internet network during the defined minutes (1 ~ 2 minutes)
14. Click the Start Button at the left corner of windows and the Run button.
15. Enter a command "cmd" and find out "DOS Command window"
16. Enter a ping command "ping –t < Destination IP address > "
17. You can see Ping response from the destination.
18. After the defined ending time, Ctrl + "C" and record the ping response result.
19. Perform the FTP Download/Upload Test with the Test server through the Network Center.
20. Alternatively, you can access directly a commercial web site with a web browser in a test laptop PC.
21. Configure APU with your final setup parameters for one of both operation mode as Wi-Fi or Secure Data Mode (APU).
22. For more detail setup, Refer to the procedure 3-5(Basic Configuration) and 3-6(Advanced and Optional Configuration).

Procedure 3-2
CSU Basic configuration and Operation Test

Action

| Step	Action

1. Connect the Ethernet cable(straight) between Laptop PC and CSU via POE Injector.
2. Launch the Configurator by either double clicking the WLAN Cable AP Configurator icon in your desktop or by opening the file config.exe from the directory "C:\Program Files\Nortel\WLAN Cable AP Configurator" where software is installed
3. The Configurator will be opended and the IP Address for your APU and Test CSU (and the IP addresses for any other devices in your network) appears in the Configurator window as shown below.

Figure 4-9
Configurator Starting Window
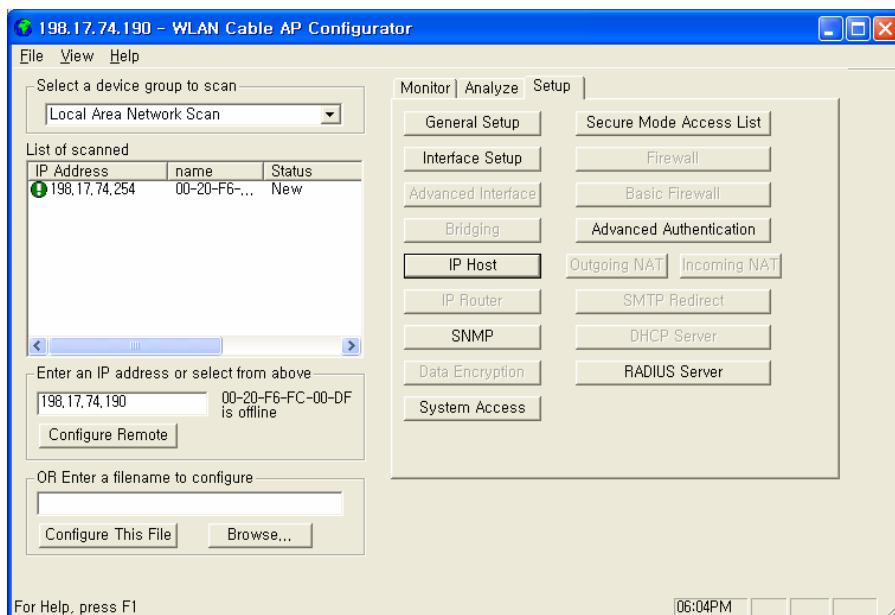

4. Note the device in the List of Scanned Devices window showing the green exclamation point"198.17.74.254". This is the device(CSU) you need to configure. Right click on this device, and then select Configure This Device. The Change IP window is displayed, as shown in the following screenshot.

Figure 4-10
IP setup dialog box
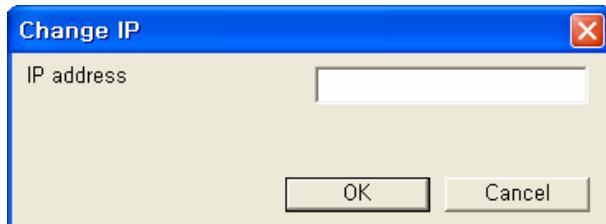

5. Enter an IP address that will be local to the IP of the PC/laptop running the Configurator, and then click the OK button. The main window is redisplayed.

    For example, In case the IP address of Laptop computer is 192.168.0.100/24, that of CSU will be allowable in 192.168.0.1/24 ~ 192.168.0.254/24 as IP address subnet group.

    Note: The IP address to enter should be included in the same subnet area with PC/Laptop Computer for access to CSU.

6. The SNMP Password dialog box is displayed, as shown below.

Figure 4-11
SNMP Read Write Password dialog box

7. Enter a proper password in the basic SNMP password box.
8. Click the OK button.
9. The Interface Setup screen is enabled and displayed, as shown in the Figure 4-12
10. Click the Interface Setup button. The Interface Setup screen is displayed, as shown in Figure 4-13. And you do not need to set up the Ethernet Interface.
11. If you have an 802.11b radio card, click the Setup 2 button to set up the 802.11b interface.
12. Click the Setup 2 button. The IEEE 802.11 Setup screen is displayed, as shown in Figure 4-14.

**Figure 4-12**
AP Configurator Main window
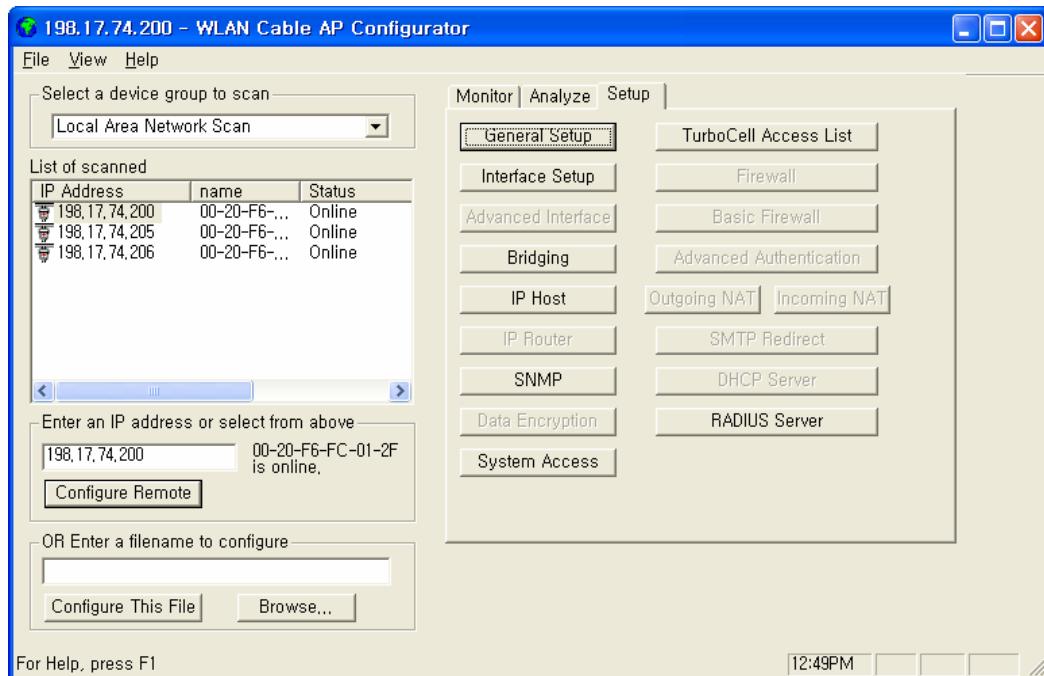

Figure 4-13
**Interface setup dialog box**
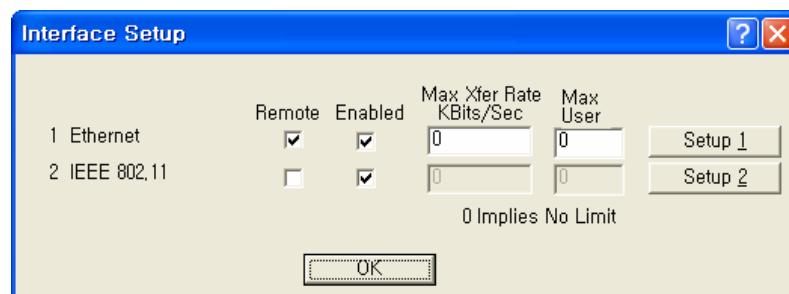

13. Make sure CSU Secure Data Mode in the left portion of Mode Selection is selected.
14. Select the Enable Signal Quality Front Panel Display checkbox if your unit has a front panel display that is capable of displaying the signal quality.

Figure 4-14
Interface setup dialog box
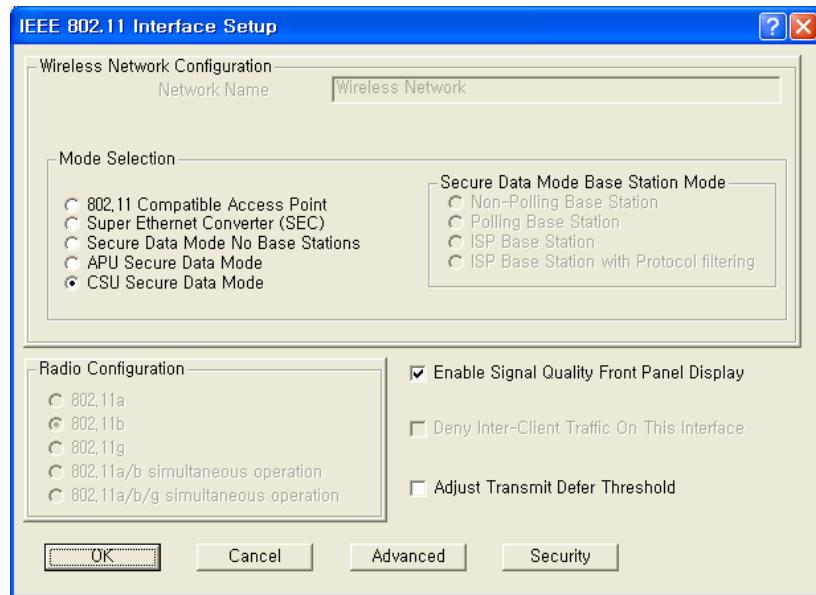

15. Click the Advanced button for setting up a crucial parameters as Radio Frequency, Transmit Rate(Bandwidth), Network ID
16. The 802.11b Advanced Setup screen for a Secure Data Mode is shown below.

Figure 4-15
Advanced setup dialog box
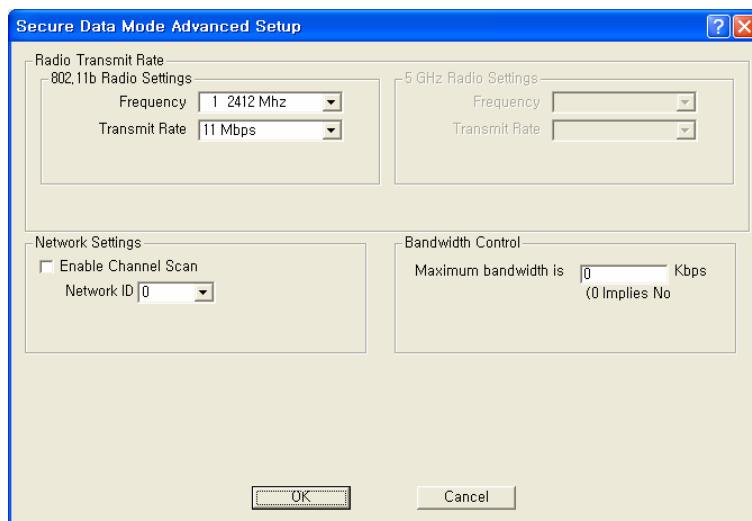

17. Select Frequency and Transmit Rate in 802.11b Radio Setting.
18. Select Network ID in Network Settings
19. In case you know only Network ID, enable the auto channel scan by checking the checkbox in the networks setting box.

20. Please see the appendix G "Wireless Network Planning".

Note: the Secure Data Mode network ID number (0-15) is used to differentiate between multiple Secure Data Mode stations using the same System Access Pass Phrase. This is used to allow a Secure Data Mode CSU to specify the APU that it wants to connect to if two APU can be seen by the same CSU. Generally, this value should be the same as the Channel Number.

Note: Radio Transmit Rate should be chosen in the below list while considering the service level of the user.
- Auto-select (IEEE 802.11 only)
- Low (1 Mbps)
- Standard (2 Mbps)
- Medium (5.5 Mbps)
- High (11 Mbps)

Note: The channel/frequency values are usually determined by network administrators. If you set the channel and frequency ensure that there are at least four numerical channels difference between two overlapping cells to avoid interference. For example, channels 1, 6 and 11 don't overlap, but channels 1 and 3 will do.

21. Click the Setup → IP Setup button. The IP Setup screen is displayed, as shown below.

Note: The IP Setup screen allows you to set the Secure Data Mode Station's IP Addressing information. The Secure Data Mode Station must have an IP address assigned to it if you wish to connect to it using the Configurator tool, which makes use of SNMP to connect to the Secure Data Mode Station.

22. Select "2 IEEE 802.11" as the interface which is used to get DHCP IP address from DHCP Server.

Note: You can choose to set up the APU to obtain an IP address from DHCP server. If you select this option, you must also choose the interface on which you would like the APU to send the request. This option causes your APU to send a broadcast request for its IP address, subnet mask, and default router over the given interface at APU startup time. If you select the DHCP option, it is recommended (though not required) that you set up your DHCP server to always provide the same IP address to this Secure Data Mode Station system.

23. For more detail setup, Refer to the procedure 3-5(Basic Configuration) and 3-6(Advanced and Optional Configuration).

Figure 4-16
IP setup dialog box
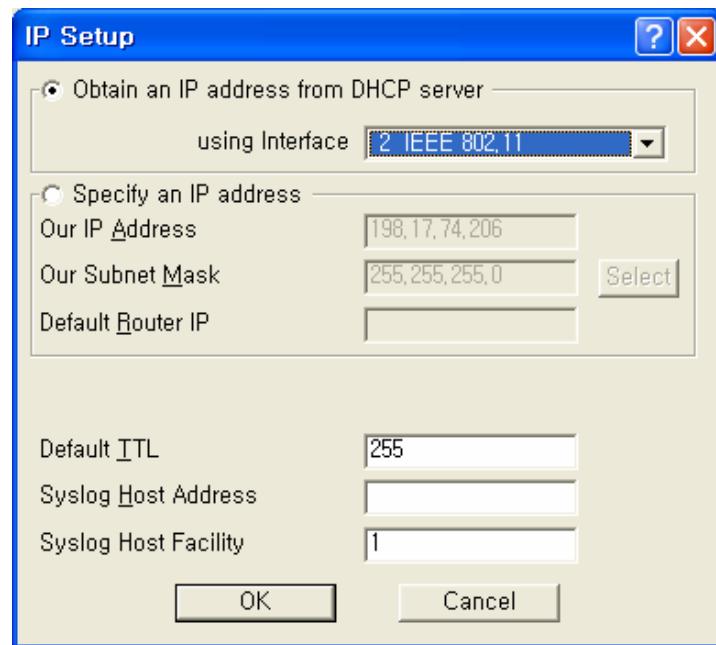

Procedure 3-3
Testing the connection between APU and CSU

The Configurator's Wireless Link Test screen is used to diagnose the wireless link quality between your APU and any CSU associated with the APU.

The Wireless Link Test displays the diagnostic counters that apply to the radio interface and a single remote station connected to this APU.

To assess the overall wireless performance in the wireless area served by the APU, you might need to run Remote Link Tests with multiple CSU (one by one).

Action

Step	Action

1. Prepare a Laptop computer and configure the test network as shown in Figure 4-17.
2. Prepare a CSU module, POE Injector and Power supply system like a Power booster in a vehicle or regular power outlet in home.

Note: Make sure that CSU and Laptop computer are set to DHCP Client so that they can get IP address dynamically through APU from Server.

3. Be aware that the CSU has the same parameters with APU to test in the operation mode as followed below

Table 4-1
System Main Parameters

Parameter	APU	CSU
IP address	DHCP Client	DHCP Client
Read Write Password	User-specific	User-specific
SNMP Secure Configuration Password	User-specific	User-specific
Mode Selection	APU Secure Data Mode	CSU Secure Data Mode
Base Station Mode	Polling(Primary)	N/A
Frequency	User-specific	Auto scanning support
Transmit Rate	User-specific	User-specific
Network ID	User-specific	User-specific
Others	User-specific	User-specific

Figure 4-17
Test Network Configuration (Maintenance & Testing Setup)
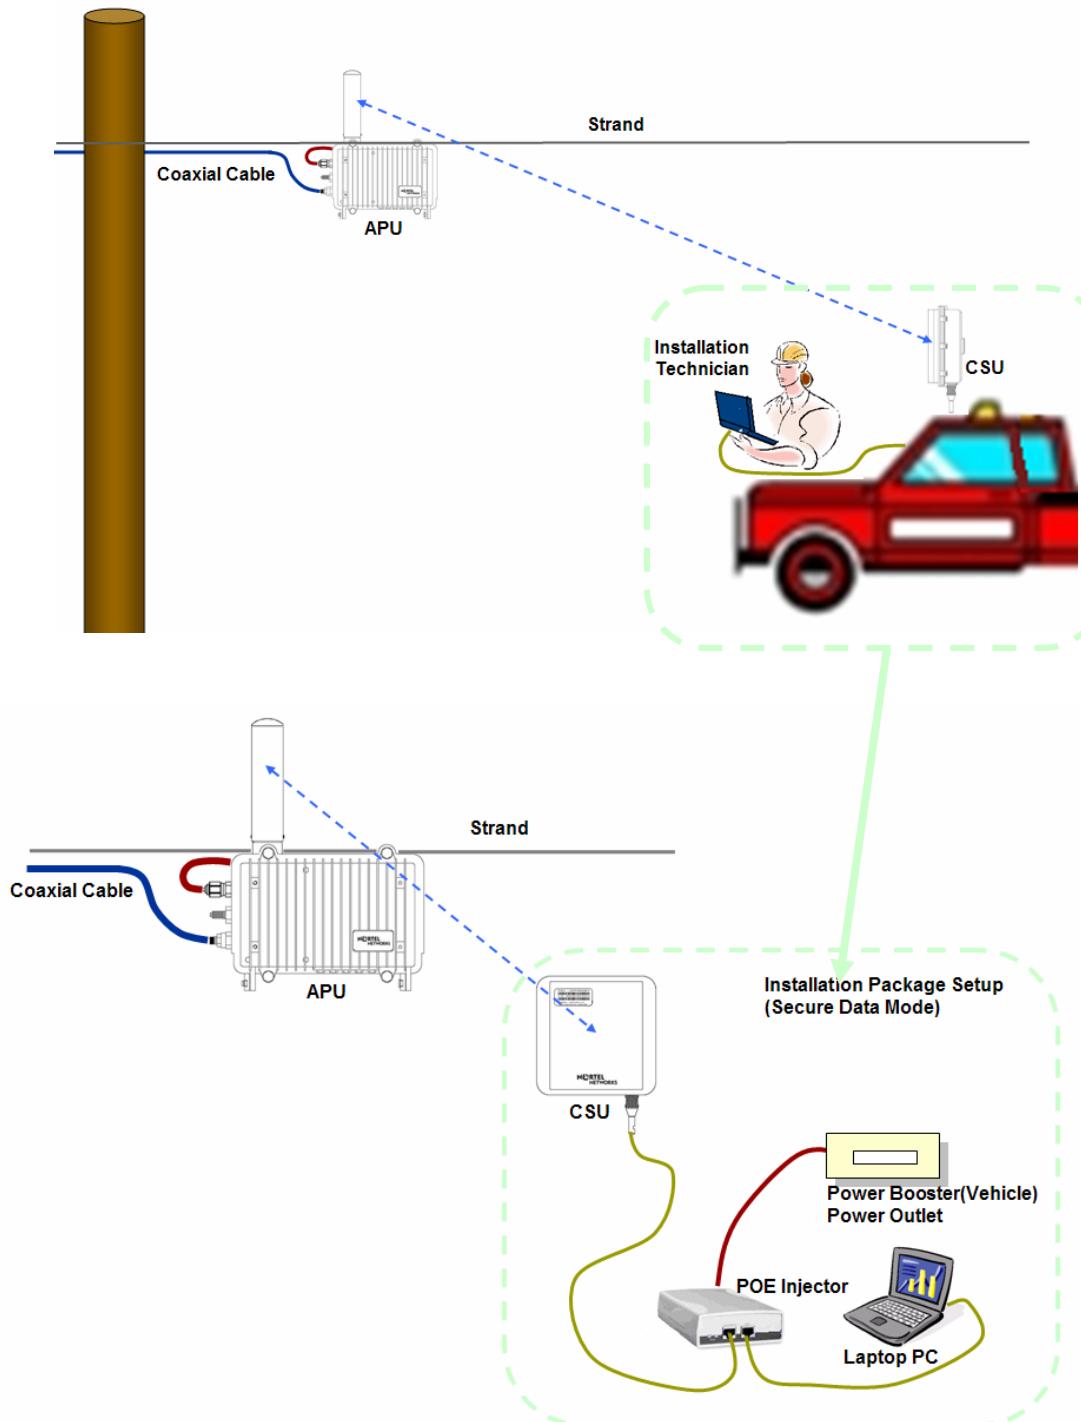

4. Launch the Configurator by either double clicking the WLAN Cable AP Configurator icon in your desktop or by opening the file config.exe from the directory "C:\Program Files\Nortel\WLAN Cable AP Configurator" where software is installed

5. The Configurator runs and the IP Address for your APU and Test CSU (and the IP addresses for any other devices in your network) appears in the Configurator window, as shown below.

Figure 4-18
Configurator Starting Window
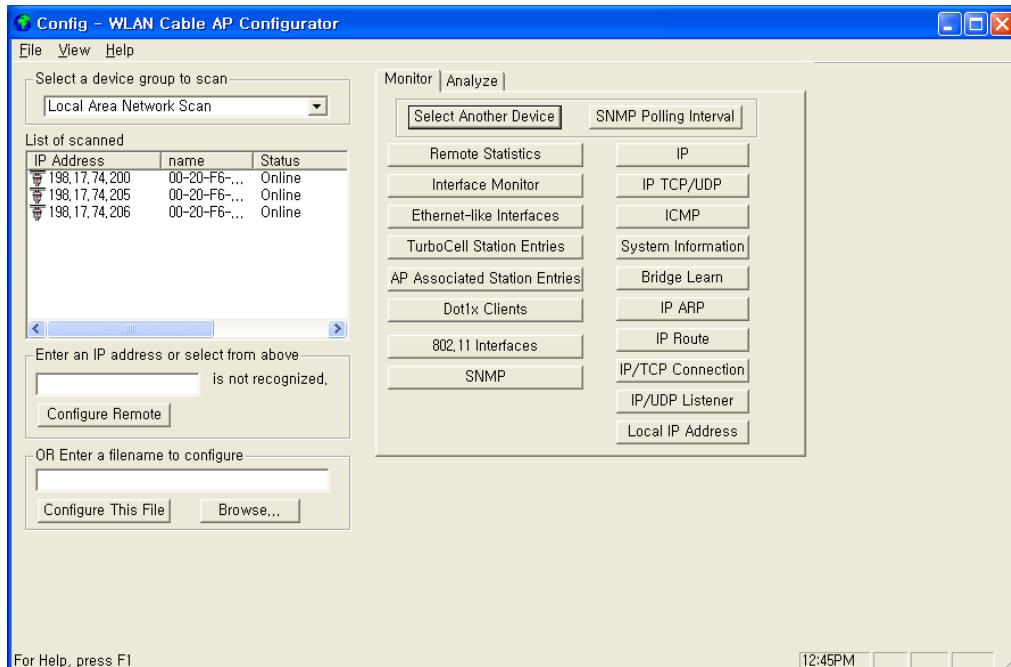

6. Make sure that the laptop computer gets an IP address from the DHCP server at Network Center by checking an IP address list box at the left side of the configurator window.
7. Check if a Dynamic IP address is allocated APU and Test CSU
8. If the APU you wish to configure is on the same network subnet as your computer, you can select it from the list that is automatically displayed in the IP Address window. Press the<F5> key to refresh the scan list. Alternately, you can also right click anywhere in the scan window and select Re-scan local network.

Note: To differentiate the APU to be configured, you should check the AP MAC address of APU which is printed on the label attached on the side of APU.

9. If you can find out the IP address of APU on the IP address window, Move a mouse pointer on the IP address.

Figure 4-19
IP address list box
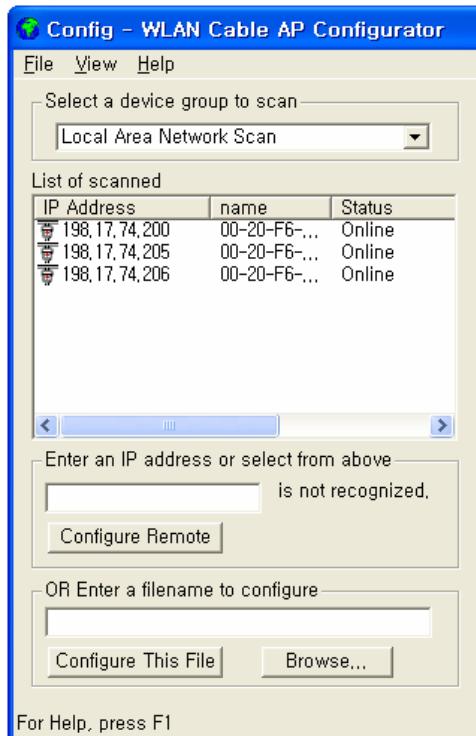

10. Right click on the IP address, and click the Configure button below the list box on the left side of a configurator window. The Read/Write Password screen is displayed, as shown below.

Figure 4-20
SNMP Password (Read/Write)

11. Enter the password "public" for the device you have selected at both text boxes, and then click the OK button.
12. If the Setup tab is displayed in the main window as shown below, SNMP checking is a success.

Figure 4-21
Setup Tab
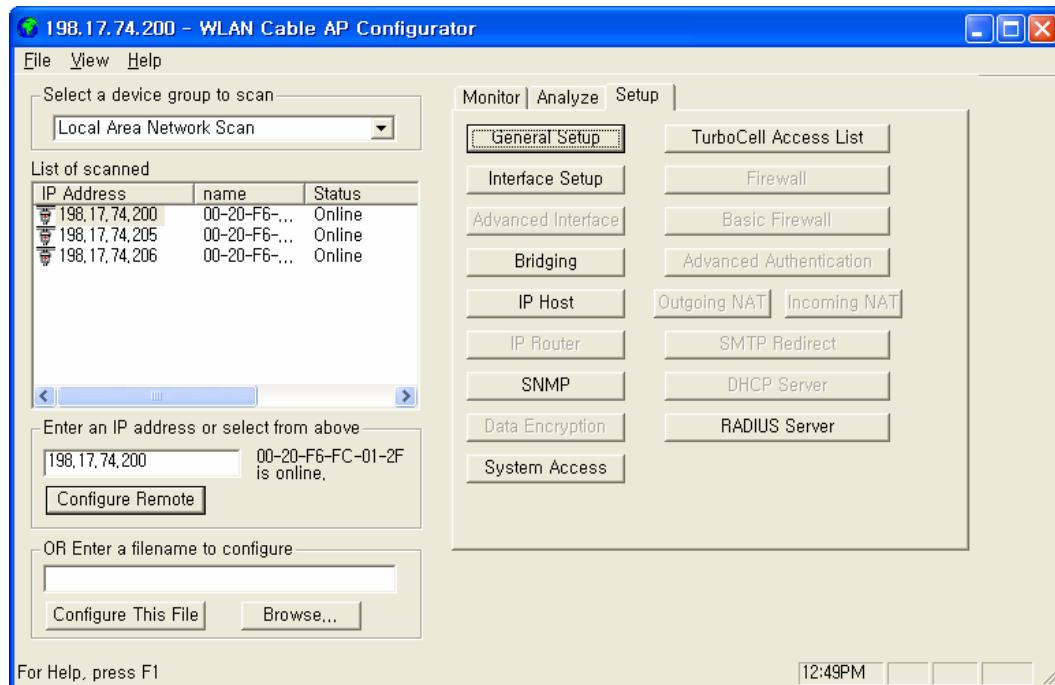

> **Note:** When you test the APU with Test CSU, you don't have to change the parameters of APU with AP configurator. But, after all test completed, you should configure APU according to your local network design idea.

> 13. Select Wireless Link Test from the Analyze Tab. The Enter IP Address screen is displayed, as shown below.

Figure 4-22
SNMP Password (Read/Write)

> 14. Enter the Remote IP Address and Read/Write password for the wireless station you wish to test. The Select a Remote Link Partner screen is displayed, as shown below.

Figure 4-23
Remote Link List window
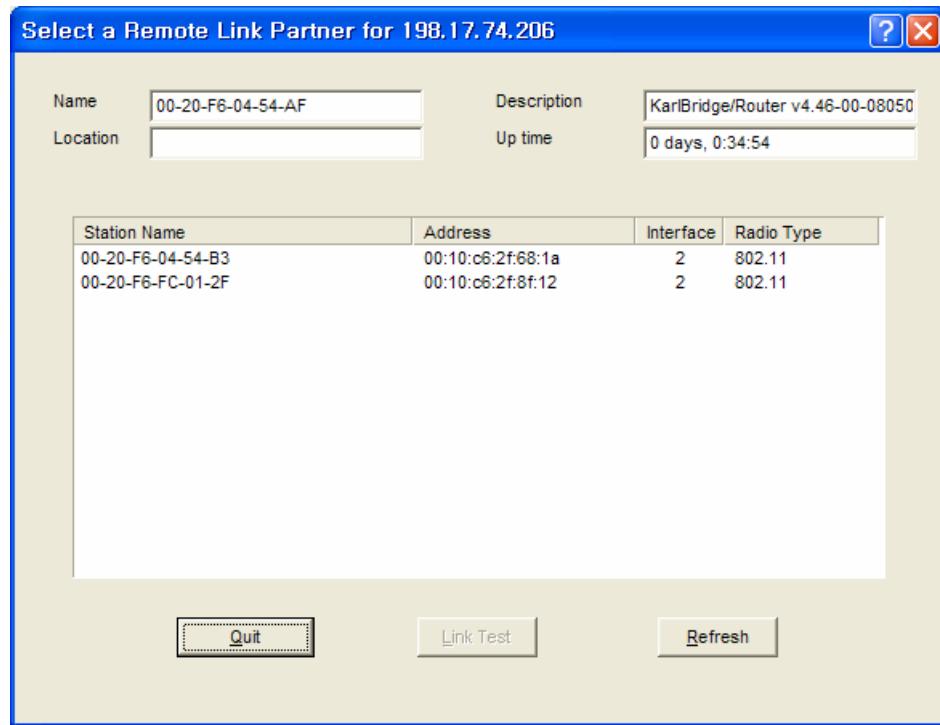

15. From the list of station names, select the remote station or client you wish to test. Select a station from the list, and then click on the Link Test button to perform a link test.

    Note: Clicking the Explore button refreshes the list of stations that can be selected.

16. Click the Link Test button to start the link test.

    Note: When you open this screen, the base station will need approximately 20 seconds to build the list of stations and forward this information to your configurator station. Due to the dynamic characteristics of mobile wireless stations, the base station will rebuild the list of connected stations each time you select a different station, or after clicking the Explore button. If this screen does not display any station, there might be no wireless station up and running in the vicinity of the selected base station.

17. The Remote Link Test screen displays the results of your wireless link test, as shown below.

Figure 4-24
Remote Link Test Status Window
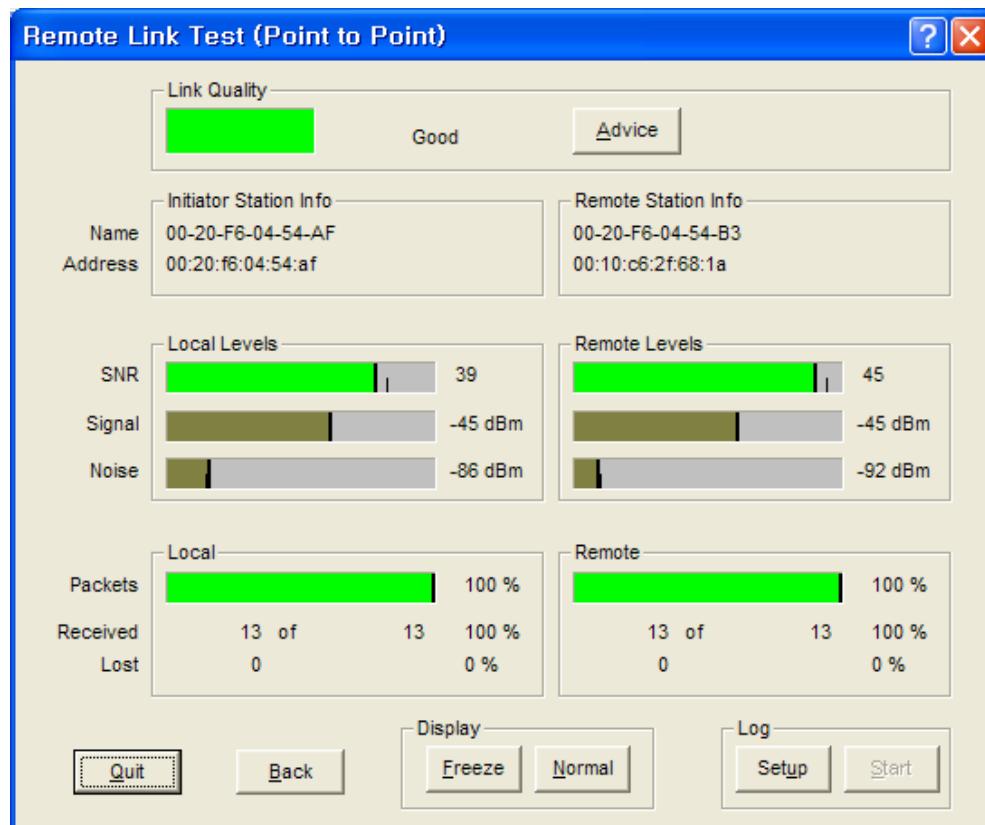

18. The advice button enables you to investigate the outcome of the Remote Link Test assessment in more detail and provides you with troubleshooting hints to improve the quality of the link between the two remote nodes. The following table summarizes the possible results of clicking the Advice button, and what action is warranted based on the results:

19. It is necessary that you adjust the vertical tilt and horizontal angle toward APU at the mounting point of CSU, while monitoring the RF link quality status window so that SNR and Link status bar keep a best quality.

Table 4-2
Radio Link Status

Status	Risk	Action
Excellent	None	You do not need to perform further diagnostics.
Good	None	You may try to optimize antenna placement to see whether this will improve the Link Quality result.
Marginal	Communication is still possible, but this situation may affect the unit's performance.	- View Link Test Details to verify. The unit may have to retransmit lost packets. - Verify the Signal Level indicator. A low Signal Level indicates the unit has moved away from the base station. - View Link Test Details to verify the Noise Level indicator. A high Noise Level indicates a source of interference in the signal path between the unit and the base station. - Select another unit to verify if the base station is functioning properly. - Try to optimize antenna placement to improve the Signal Level or move it away from the source of interference.
"No Connection"	Communication is no longer possible. If the unit was in the process of transferring files, data may not have arrived at the intended destination, or it may have been corrupted.	- View Link Test Details to verify the Signal Level indicator. A low Signal Level indicates the unit has moved away from the base station. - View Link Test Details to verify the Noise Level indicator. A high Noise Level indicates a source of interference in the signal path between the unit and the base station. - Select another unit to verify if the base station is functioning properly. - Try to optimize antenna placement to improve the Signal Level or move it away from the source of interference.
Quality Indicator is	None. The base station may be busy collecting	If the indicator remains blank, click the other button to return to the

Black	diagnostic measurement results from the unit.	Select a Remote Link Partner screen. Click the Explore button to refresh the list of Link Test Partners. If the initial partner no longer appears, it may have been switched off, or have been moved outside the range of the selected Initiator Station. ▪ Select another Link Test Partner to verify if the base station is functioning properly.

Procedure 3-4
Testing Wireless Network Performance

FTP Up/Download Test

Action

Step	Action
1.	Launch the Configurator by either double clicking the WLAN Cable AP Configurator icon in your desktop or by opening the file config.exe from the directory "C:\Program Files\Nortel\WLAN Cable AP Configurator" where software is installed
2.	The Configurator runs and the IP Address for your APU and Test CSU (and the IP addresses for any other devices in your network) appears in the Configurator window

Figure 4-25
Configurator Starting Window
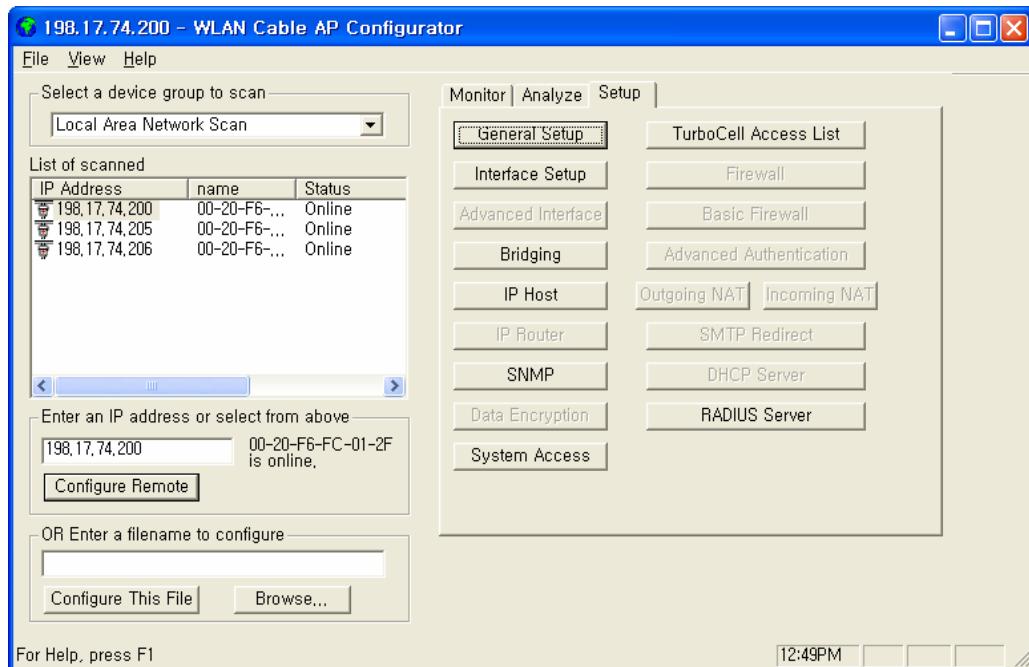

Step	Action
3.	Make sure that the laptop computer gets an IP address from the DHCP server at Network Center by checking an IP address list box at the left side of the configurator window.
4.	Check if a Dynamic IP address is allocated at APU

5. If the APU you wish to configure is on the same network subnet as your computer, you can select it from the list that is automatically displayed in the IP Address window. Press the<F5> key to refresh the scan list. Alternately, you can also right click anywhere in the scan window and select Re-scan local network.
6. If you can find out the IP address of APU on the IP address window, Move a mouse pointer on the IP address.

Figure 4-26
IP address list box
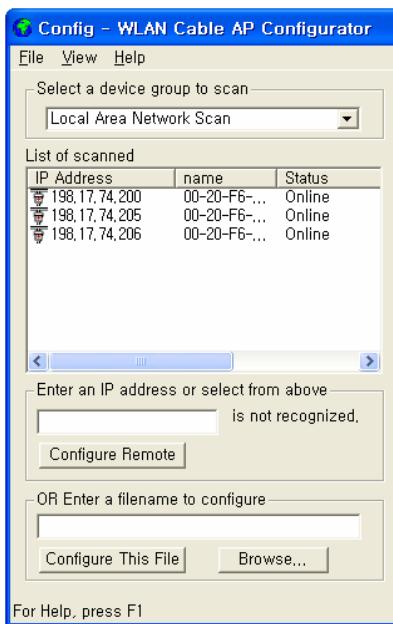

7. Perform Ping Test to the specific IP address of network entity which is located at the public internet network during the typical minutes(1 ~ 2 minutes)
8. Click the Start Button at the left corner of windows and the Run button.
9. Enter a command "cmd" and find out "DOS Command window"
10. Enter a ping command "ping –t < Destination IP address > "
11. You can see Ping response from the destination.
12. After the defined ending time, Ctrl + "C" and record the ping response result.
13. Perform the FTP Download/Upload Test with the Test server through the Network Center.

Testing Wireless Network Performance (Ping Fill Test)

Action

Step	Action

1. On the Analyze tab, click the Ping Fill Test button. The Enter IP Address screen is displayed.

   Note: The above IP address should be that of CSU (Client of APU) which can get the IP address list box at AP configurator.

**Figure 4-27
IP Address Tab**

2. Enter the IP address and Read/Write Password of the Internet host with which you would like to test throughput, and click the OK button. The Ping Fill Test Parameters screen is displayed. .

   Note: To test wireless performance, the target system can be one of the APU Secure Data Mode station's clients. You can also use a wired host to test wired interface performance.

3. Enter the Test Window Size, Max Packets, and Test Running Time.
   Ex) Packet Length: 60, Window size: 80, Maximum Packets: 20,
       Number of Second: 5
4. Click the OK button. You will see some warning messages, and then the Ping Fill test will run. The results of the test are then displayed in the Ping Fill Results screen.
5. Choosing the correct parameters is crucial to obtain accurate Ping Fill Test results. To find out more about each of the parameters, click in the fields shown in the screenshot below.

Figure 4-28
Ping Fill Test Parameters
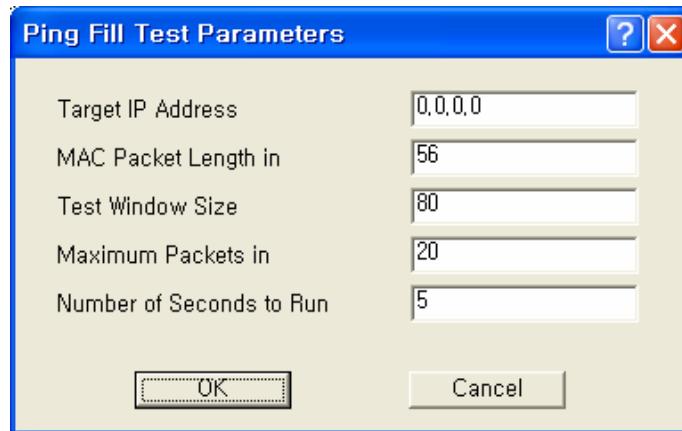

6. As soon as Ping Fill test is over, you can see result windows as below.
7. Record Average Transfer Rate of the result items
   It is recommended that the result window to be captured as a picture and saved in the file.

Figure 4-29
Ping Fill Test Results Window
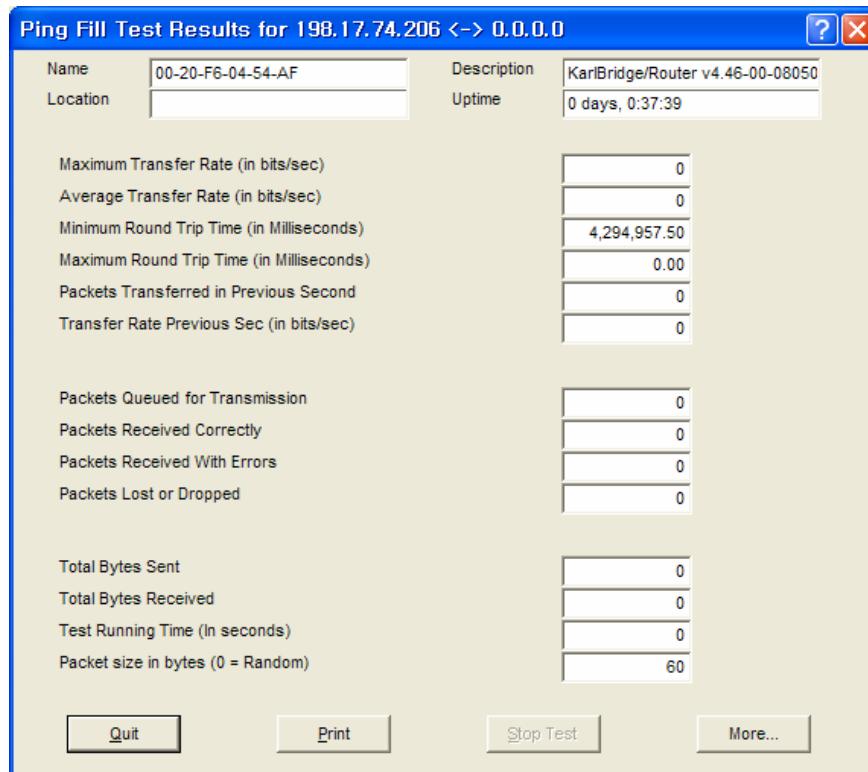

Procedure 3-5
Basic Configuration

Set Up General Configuration Options

The Setup tab is used to define the configuration options for the device, and the General Setup screen is used to enable various setup options. Click on the Setup tab, then click the General Setup button to display the General Setup screen, shown below:

Figure 4-30
General Setup window
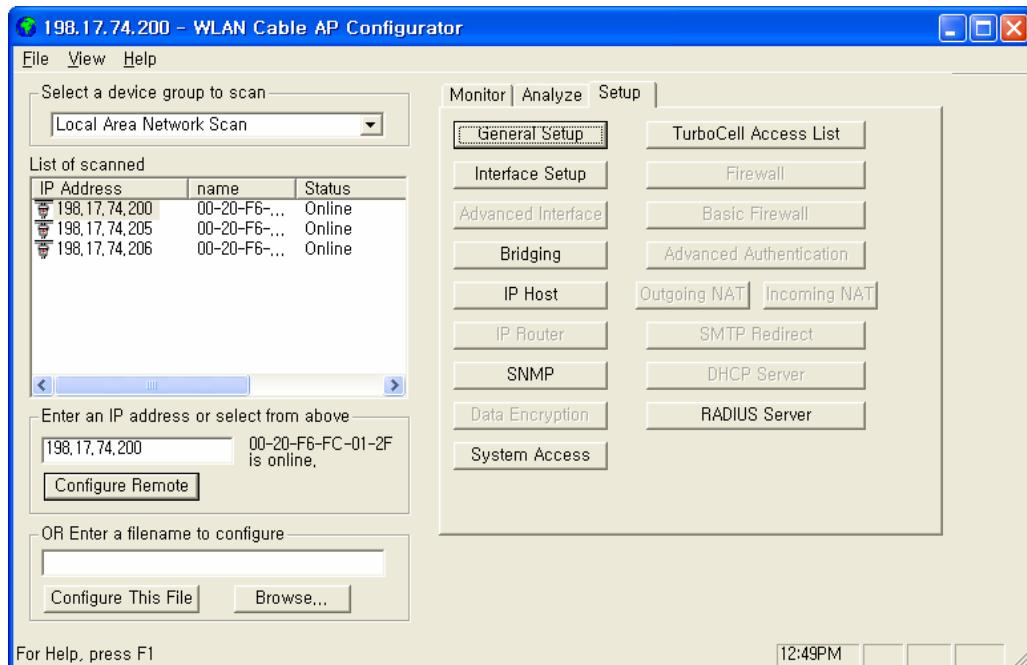

Note: This menu has been modified for use in this manual. This menu has all supported features checked (enabled) and is NOT typical of the menu you will see. Each of the fields on the screen is explained below.

Figure 4-31
General Setup window
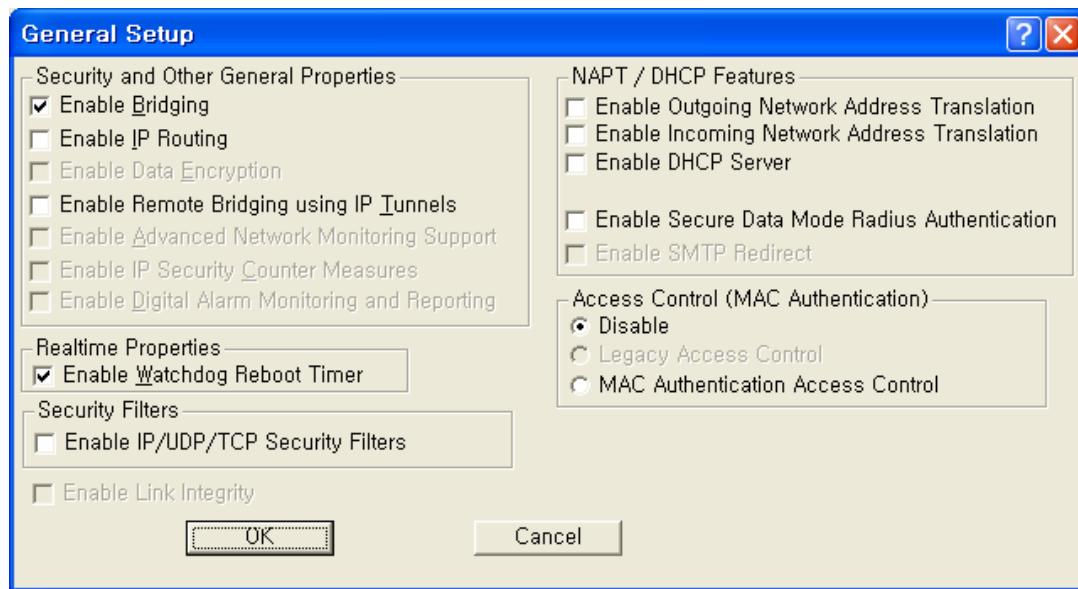

Enable Bridging

Selecting this checkbox in General Setup will allow you to access the
Bridge Setup screen, which you can use to enable your device's
transparent Ethernet bridging feature. This allows for the transference of
Ethernet packets between physical networks connected directly to the
base station.

If enabled, the base station will transfer Ethernet packets from one
interface to the other (for example, between the wireless and the wired
networks). The default behavior is to bridge all Ethernet protocols. You
can set which Ethernet protocols to bridge or deny, as well as, Ethernet
stations that will be allowed or disallowed to send packets over the
bridge using Bridge Setup from the Setup tab.

If disabled, only IP packets with correct IP Routes set up in IP Router
Setup will be bridged between the base station's various interfaces;
general Ethernet packets will not be transferred across the base station.
This would be useful in a situation where you want to enable IP traffic,
but not general Ethernet traffic between (sub) networks.

Enable IP Routing

Selecting this checkbox in General Setup will enable your hardware
device to route IP packets between its various interfaces.

If enabled, you will need to set up routes on the IP Routing screen or you will not be able to access your hardware unit when you exit the Configurator program.

Enable Remote Bridging Using IP Tunnels

This option allows you to encapsulate Ethernet packets of any protocol in IP and then send them to another Secure Data Mode Bridge/Router to de-encapsulation. Select this checkbox to enable this capability.
Some versions of the Secure Data Mode Station support a special feature which will enable Ethernet packets of any protocol type to be encapsulated in IP and then sent to other Secure Data Mode Stations for de-encapsulation. This method can be used to set up "virtual" Ethernet LANs between several points using the IP network as the transport layer. This feature can be used to create a Virtual Private Network when used in conjunction with the Data Encryption option.

Enable Watchdog Reboot Timer

Select this item in General Setup to enable the watchdog timer reboot feature. If packets are not seen on the network for more than 10 minutes (a very rare occurrence), the Secure Data Mode Station will reboot itself. Once it has rebooted, the 10 minute reboot timer will not activate again until a packet has been seen on one of the interfaces. This is to ensure that only one reboot will occur if the entire network is truly shut down.

Enable IP UDP/TCP Security Filters

Select this option in General Setup to enable the base station's Firewall (IP Security Filter) features. You can set the base station to explicitly or implicitly allow or deny IP connections to specific UDP or TCP ports, and/or between specific IP addresses or subnets. For more information, see Firewall Setup.
Note: This option is only available when the MAC Authentication Access Control button has been selected on the General Setup screen.

Enable Outgoing Network Address Translation

Select this checkbox if you will be using Outgoing NAT to multiplex traffic from all the computers on your internet network through the Secure Data Mode Bridge/Router.
Outgoing Network Address Translation (NAT) allows multiple computers to share a single IP address to connect to an IP network, including the Internet. This allows homes, small businesses, and Internet Service Providers to have Internet service for all of their computers without having to pay for additional IP addresses. The NAT feature

serves as a simple firewall for incoming connections, since only traffic initiated by an interior computer is permitted through the NAT.

Enable Incoming Network Address Translation

Select this checkbox if you will be using Incoming NAT to multiplex traffic from the network to all the computers on the internal network. Incoming Network Address Translations (NAT) is used to redirect requests to servers in the local address space based on the port of the request. If, for example, the client at local address 10.0.1.2 is serving web pages, and a request comes to the access point on that port for a web session, then the request will be forwarded to the web server on 10.0.1.2. The server will respond with the web page to the address of the original request.

Note: Incoming NAT only needs to be configured if servers in the local (private) address space need to connect with clients in the global (public) address space.

Enable DHCP Server

Select this checkbox if you are using the Secure Data Mode Bridge/ Router to provide DHCP information to the computers on your network.

Note: If you do not check this option, you will not be able to access the DHCP Server screen.

Enable Secure Data Mode Radius Authentication

Select this checkbox if you wish to enable RADIUS authentication for your Secure Data Mode stations.

Enable Network Address Translation Redirector

Select this checkbox if you wish to enable network address translation (NAT) redirection, which is used to forward the packets sent to a particular port number to a specified IP address, regardless of the original destination IP address.

Access Control Buttons

The access control buttons determine how authentication is controlled. There are three possible means of authentication control:
- Disable - Selecting Disable turns off MAC authentication entirely.
- Legacy Access Control - Selecting Legacy Access Control enables access to the Access Control Setup screen and disables access to the Advanced Authentication screen

- ▪ MAC Authentication Access Control - Selecting MAC Authentication Access Control enables access to the Advanced Authentication Setup screen, which provides more detailed MAC authentication setup options, and disables access to the Access Control Setup screen.

Set Up Interfaces

Once you have enabled various configuration options, you need to define the network interfaces for your hardware device. You will typically set up one or more of the following interfaces:
As the name suggests, the Interface Setup screen is used to set up network interfaces. From the Setup tab, click the Interface Setup button. The Interface Setup screen is displayed, as shown below:

Figure 4-32
Interface setup window

Interface (APU)
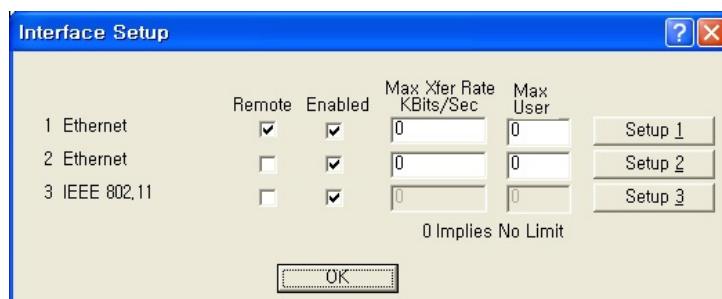

Interface (CSU)
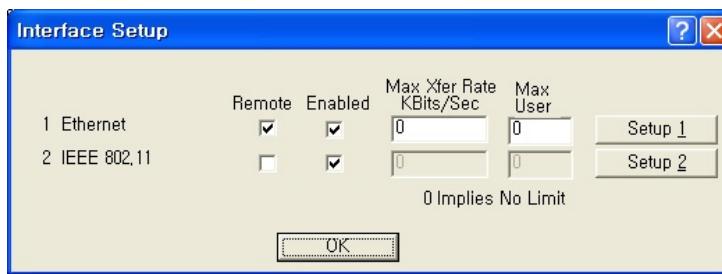

The following rules apply for setting up network interfaces:

- ▪ You do not need to set up the Ethernet Interface.
- ▪ If you have an 802.11b radio card, click the Setup 2 button to set up the 802.11b interface.

Remote Checkbox **--** Select this checkbox if all traffic coming in on this interface is to be viewed as remote traffic for firewall, bridging, filtering, and routing purposes. If this checkbox is not selected, then all traffic on this interface will be considered local traffic. Note that the "Remote" designation is significant only for the Security filters, and does not imply physical location. The security filters will pass (permit) or drop (deny) packets of particular types from being forwarded between interfaces designated as "Local" (unchecked) and those designated as "Remote".

Note: At least one enabled interface must be a remote interface.

Enabled -- Select this checkbox if this interface should be enabled. If this box is not selected, then the base station will disable the interface and it will not be used, and the interface itself will be "down" from an administrative standpoint.

Note: At least one enabled interface must be a remote interface.

Maximum Transfer Rate (Kbits/sec) -- The maximum transfer rate is the number of bits that can be used for sending and receiving packets. If you wish to limit the maximum data transfer rate for a particular interface, enter the maximum number of kilobits per second that can be transmitted from and to the base station. This helps to reduce the risk of over-powering remote sites and to limit the bandwidth used by a particular base station.

Note: The transfer rate represents the total transfer rate for both sending and receiving packets. For example, if you set the transfer rate to 10,000 Kbits (10 Mbits) per second, then 10 Mbits represents the maximum rate available for both sending and receiving packets. Therefore, if you use 7 Mbits per second in sending the packets, then only 3 Mbits per second are available for receiving packets.

Setup 1, 2, 3-- The Setup 1, 2 buttons are used to define the available interfaces. In the screenshot shown above, clicking Setup 1 will display the Ethernet Setup screen, clicking Setup 2 will display the 802.11b Setup screen. Each of the Interface Setup screens is explained in more detail below.

Set up Ethernet

Clicking the Setup 1 button on the Interface Setup screen displays the Ethernet Setup screen.
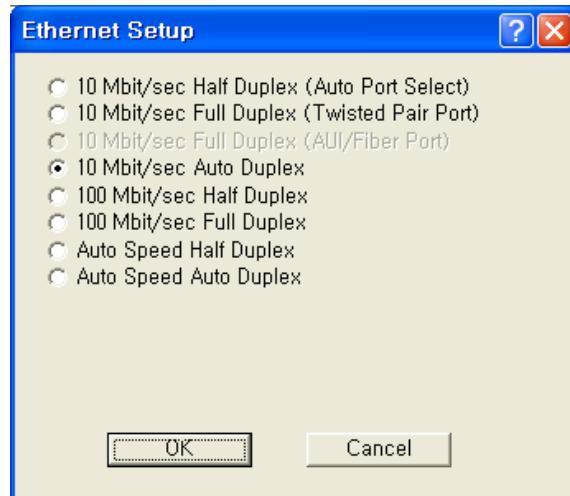

The Secure Data Mode station will automatically set up the Ethernet interface to use the type of medium that has been connected to the unit. By default, the Ethernet connection is set at 10 Mbit/sec for both half duplex and full duplex. Therefore, you do not need to configure special settings for the Ethernet hardware interface. If you wish to customize the Ethernet settings, you can change the settings listed below. However, you do not need to change any settings for your hardware device to be functional.

- The Secure Data Mode Station supports both Ethernet IEEE 802.3 and DIX Ethernet frame types.
- Protocols are set in the Interface Setup window of the Setup Tab.

Note: Do not change the default setup "10Mbit/sec Auto Duplex" in this setup window without a technical consult of manufacturer.

Ethernet Type -- The Ethernet type options provide a variety of Ethernet settings. The default value for Ethernet type will vary, depending on your hardware device. Only the settings that are enabled on your screen are supported by your particular hardware device. If your switch or Ethernet card supports different speeds, you may want to change the speed setting.

Set Up 802.11b

Clicking the Setup 2 button on the Interface Setup screen displays the 802.11b Setup screen. The 802.11b Setup screen is used to set up the interface to your 802.11b network devices.

Figure 4-34
802.11 Radio Interface Setup window (APU Secure Data Mode)
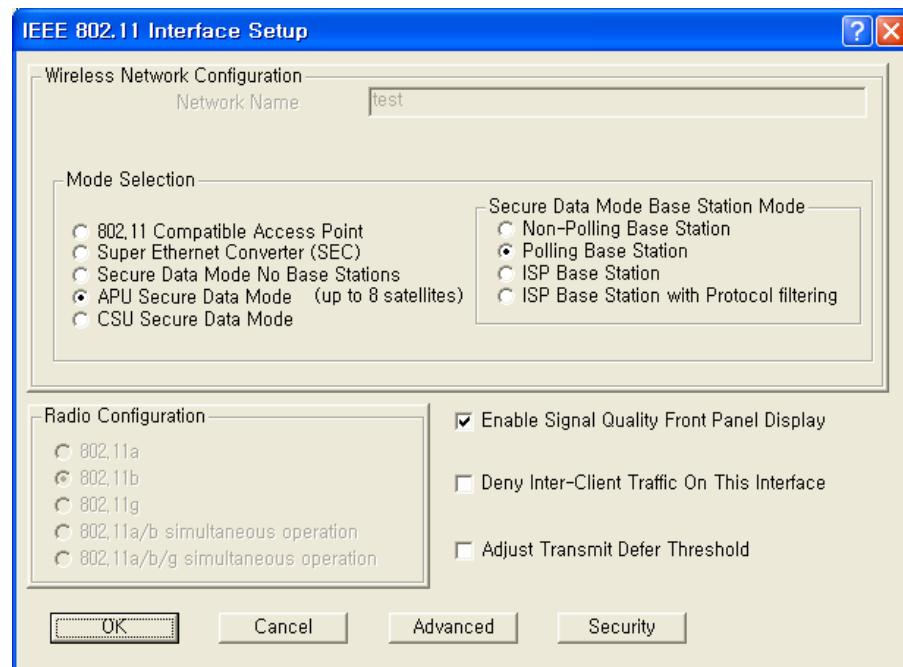

Figure 4-35
802.11 Radio Interface Setup window (APU Wi-Fi Hotspot Mode)
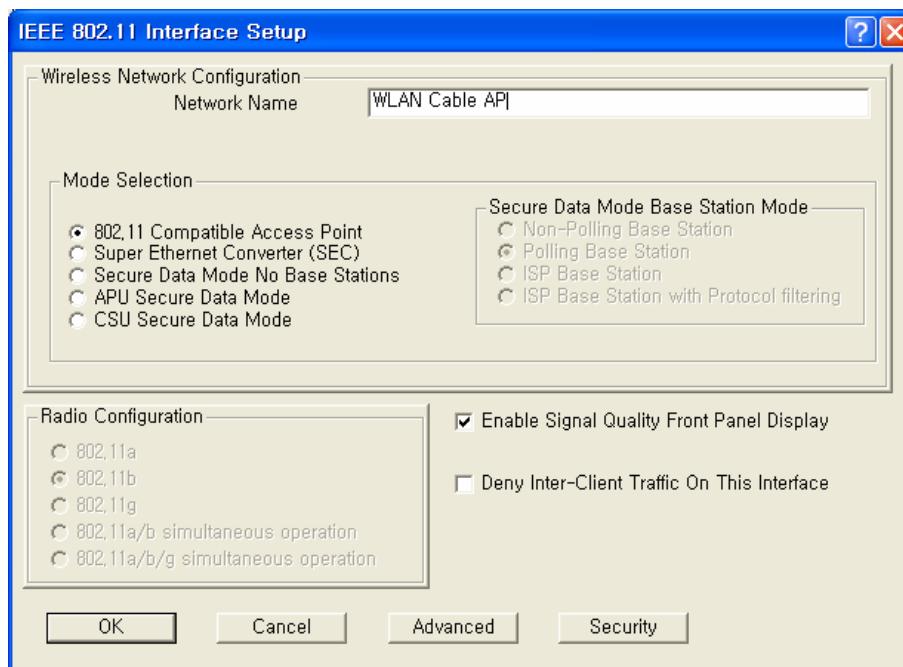

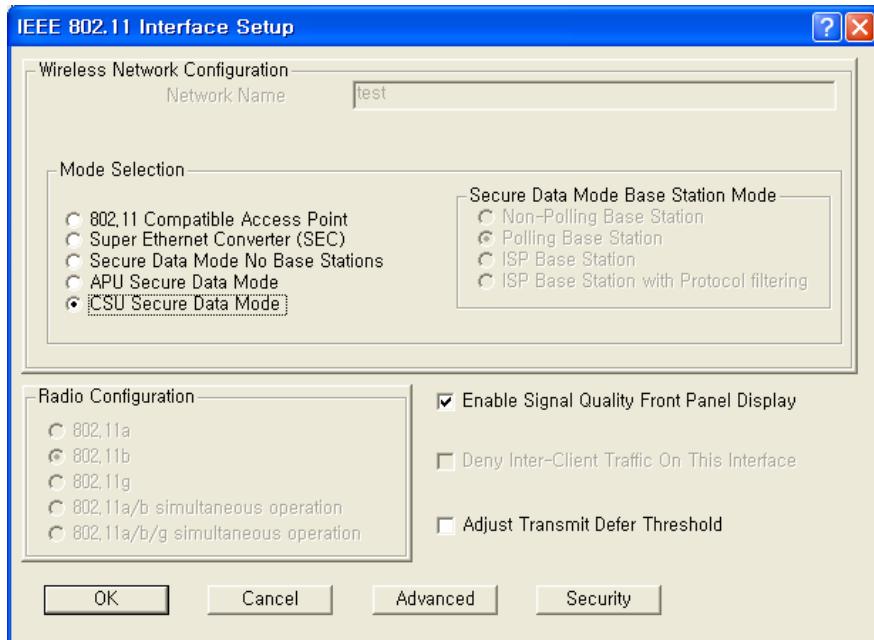

802.11b Network Name-- The 802.11b Network Name is used in standard IEEE 802.11b networks to distinguish stations in your 802.11b network from stations that belong to a neighboring 802.11 network. The value used for the radio interface on this station should be the same for all wireless stations in the 802.11b network. Only stations configured with the proper 802.11b Network Name will be able to connect to the 802.11b station's radio interface.
The Network Name can be any alphanumeric string in the range of "a" to "z," "A" to "Z" and "0" to "9," and can contain from 1 to 32 characters.

If you wish to allow access to the wireless network to be open to all wireless stations, the Network Name should be set to ANY.

Note: The Network Name is used only when the 802.11b radio interface (for example, Orinoco) is set to run in IEEE 802.11 Access Point Mode.

802.11 Compatible Access Point-- When this option is selected on the 802.11a or 802.11b Setup screen, the card attached to this interface will act as a standard 802.11a or 802.11b access point.

Use this setting when:

- Connecting to any 802.11 radios acting as mobile units
- Operating this interface for compatibility with other manufacturers' access point hardware

- Communication over the wireless network is light, or is limited primarily to one satellite

Note: When using this mode, you will not be able to connect to multiple Access Points over the same interface.

If you wish to support a LAN (either wired or wireless) connected to the far side of a remote 802.11 device, you must use a Secure Data Mode Network setup by choosing one of the Secure Data Mode Station modes (see Related Topics for more information).

The IEEE 802.11b Access Point mode is useful primarily for indoor wireless LAN's that have no hidden nodes. For wireless network infrastructure connections you should use one of the Secure Data Mode Station types.

Super Ethernet Converter-- When this option is selected, the card attached to this interface will act as a Mobile Router.

You must also uncheck the Enable Bridging checkbox in General Setup (of the Mobile Router. An Access Point acting as an IEEE Compatible Mobile Router will allow only IP traffic to be transmitted between the Remote IP LAN and the Secure Data Mode Network. The remote LAN must be using IP in order to connect to the IEEE network, but can use additional protocols as well.

In order to bridge Ethernet traffic over the wireless network between remote LANs, you must select one of the Secure Data Mode station types.

Secure Data Mode No Base Stations-- Select this option to set your 802.11b device's radio card on this interface to run as a Secure Data Mode Network without a Secure Data Mode Base Station (i.e. peer-to-peer).

Use this setting only in the rare instance when all Secure Data Mode stations are able to "see" each other (i.e., there are no hidden nodes).

When all connected Secure Data Mode Stations are not able to "'see" one another, this setting should not be used. In that case, you should set one of your Secure Data Mode Station stations to Secure Data Mode Base Station, and the others to Remote (Satellite) Secure Data Mode Stations.

APU Secure Data Mode-- Selecting this option sets the Secure Data Mode Station to run as a Secure Data Mode Base Station over the 802.11b device's radio interface. Every system that needs to connect to the wireless network must be able to connect to the Secure Data Mode Base Station.

When you select this Base Station type, you must select one of the Protocol Filtering Modes. The Protocol Filtering Mode determines how the base will interact with the satellite (slave) stations. Is it recommended that you use the Enable Filters between Slaves mode.

The possible base station modes are as follows:

Non-Polling Base Station

The non-polling Secure Data Mode Base Station Mode is provided mostly for compatibility with older Secure Data Mode Networks, but may give increased performance over other (polling) Secure Data Mode Base Station modes in a lightly loaded network, or in a network with only a few satellites.

Setting a base station to non-polling mode may increase performance in the rare case where all satellites can hear one another (i.e. there are no hidden nodes), or when there is sporadic network use. In an environment where most network traffic is with one satellite, and other satellites rarely transmit data, this setting may also increase performance. However, it is highly recommended that you select one of the polling modes.

Selecting this Secure Data Mode Base Station Mode takes full advantage of the features of a Secure Data Mode Network.

Polling Base Station

Selecting this Secure Data Mode Base Station Mode sets the Secure Data Mode Station to run as a Secure Data Mode Base Station which performs a highly optimized Nortel Networks-proprietary polling of the satellite stations for data. In the Non-Polling Base Station mode, all wireless stations must be able to 'hear' each others' traffic, or performance may degrade considerably (the hidden node problem). In polling mode, the Base Station will poll each station for data, and also offer the opportunity for 'free-for-all' sending of data at set intervals.

In conjunction with the standard features of the Secure Data Mode Network, this Secure Data Mode Base Station Mode offers a significant performance increase over other wireless protocols when the network is under heavy load.

ISP Base Station

Selecting this Secure Mode Base Station sets the Secure Mode Station to run as a base station for connections to Microsoft Windows PC Clients. This mode takes full advantage of the features of a Secure Mode Network and allows Windows clients to connect directly to the base station, eliminating the need for an Ethernet connection to a second Secure Mode Station running as a Remote Secure Mode Station.

The following Windows clients are supported:

- Windows 95a (with the Winsock 2 update)
- Windows 95b
- Windows 98
- Windows NT 4.0
- Windows XP

To filter Ethernet protocols that are transferred between the wireless stations (for example, to disable the Windows Network Neighborhood), select ISP Base Station with Protocol Filtering. Filters set in Bridge Setup... are not applied to wireless-only traffic in the non-filtering ISP Secure Data Mode Base Station Mode.

We strongly recommend that you set your Secure Data Mode Base Station to ISP Base Station with Protocol Filtering mode when connecting Windows PC Client satellites.

ISP Base Station with Protocol Filtering

Selecting this Secure Data Mode Base Station Mode gives you the same functionality of the ISP Base Station mode, with an added filtering function that applies the bridge filters set in Bridge Setup to traffic sent over the wireless network as well.

With the non-filtering ISP Secure Data Mode Base Station Mode, all traffic between two wireless stations is permitted. Bridge filters do not apply to wireless-only traffic in the non-filtering ISP Secure Data Mode Base Station Mode.
When using the ISP Base Station with Protocol Filtering setting, you can set the bridge filters so that each wireless machine (or LAN behind another connected Secure Data Mode Station) is 'hidden' from all other machines or LAN's connected to the Secure Data Mode Network. Properly setting up Protocol Filtering will disable the Windows 'Network Neighborhood' from seeing other machines connected on the wireless network.

If you do not deny IP and IP-ARP packet types in Protocol Filtering, wireless machines are still able to connect to each other via IP packets, including TCP and UDP. Permitting only IP traffic over the wireless network will allow your wireless clients to interact as if they were connected to the Internet, but not together on a private network. For added security, the firewall features of the bridge can be used to deny certain types of IP packets from flowing between the wireless stations.

We strongly recommend that you select ISP Base Station with Protocol Filtering when the Secure Data Mode Base Station will service satellites running the PC Client.

CSU Secure Data Mode-- Selecting this option in IEEE 802.11b sets the Secure Data Mode Station to Connect to an APU Secure Data Mode Station over this 802.11b device's radio interface.

To properly use this setting, you must be sure that the following items match the APU Secure Data Mode Station Settings:

- Network ID(NWID)
- System Access Pass phrase
- Frequency Channel

Enable Signal Quality Front Panel Display-- On units that have a front panel display that is capable of displaying the signal quality, selecting this checkbox will enable the signal quality display.

Deny Inter-Client Traffic on this Interface-- Select this checkbox if you wish to prevent wireless stations from sending packet directly to each other. Usually, the AP will repeat station-to-station traffic and will not send it to the bridge and firewall filters. This is because bridging routines historically work between physical interfaces only.

Since an Ethernet packet sent between two Ethernet hosts on the same Ethernet subnet will automatically be seen by the destination host—with wireless, the packet must be repeated by the AP. This turns off the AP's packet repeating code.

Secure Data Mode Advanced Setup

Clicking the Advanced Button on the 802.11b Setup screen displays the 802.11b Advanced Setup screen, which allows you to configure more options related to the setup of your and 802.11b network devices.

The appearance of the 802.11b Setup screen varies depending on which options are set on the 802.11b Setup screen. The 802.11b Advanced Setup screen for a Secure Data Mode Base Station is shown below.

Figure 4-37
Secure Data Mode Advanced Setup window
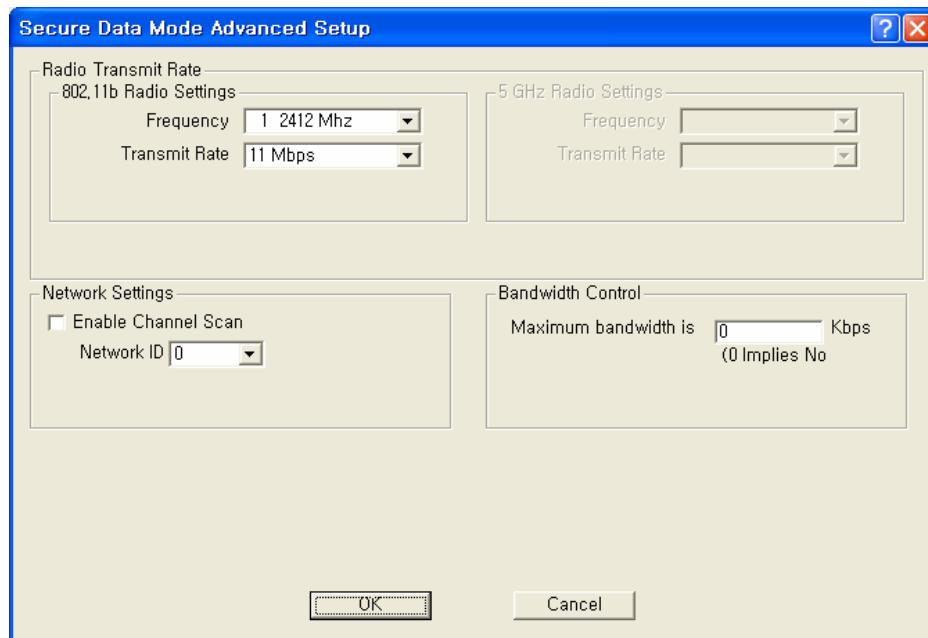

The 802.11b Secure Data Mode Base Station Advanced Setup screen is used to set up advanced features for an 802.11b Secure Data Mode base station.

Network ID-- Enter the Secure Data Mode network ID number (0-15) used to differentiate between multiple Secure Data Mode stations using the same System Access Pass Phrase. This is used to allow a Secure Data Mode satellite to specify the Base Station it wants to connect to if two base stations can be seen by the same satellite. Generally, this value should be the same as the Channel Number.

Radio Transmit Rate-- Select the radio bit rate used to transmit. Your choices are:

- Auto-select (IEEE 802.11 only)
- Low (1 Mbps)
- Standard (2 Mbps)
- Medium (5.5 Mbps)
- High (11 Mbps)

A lower signal will increase the noise. In essence, the poorer the signal-to-noise ratio, the lower this rate should be set.

Note: The transmit rate affects only the transmissions made by this station.

802.11b Frequency Setup-- Clicking the Frequency button on the 802.11b Setup screen displays the 802.11b Frequency Setup screen, which allows you to set the Frequency Channel for your 802.11b radio card.

The 802.11b Frequency Setup screen is used to change the channel and frequency for one of the remote devices on your network. Note that this screen is only accessible if you have identified remote devices in your network. If all devices are in your local network, then the Frequency Setup screen is unavailable.

Channel/Frequency-- Select the channel and frequency for the remote device from the drop-down list. See Frequency Channels for a more detailed explanation of the frequency channels.

Note: The channel/frequency values are usually determined by network administrators. If you set the channel and frequency ensure that there are at least four numerical channels difference between two overlapping cells to avoid interference. For example, channels 1, 6 and 11 don't overlap, but channels 1 and 3 do.

Hotspot Mode Advanced Setup

Clicking the Advanced Button on the 802.11b Setup screen displays the 802.11b Advanced Setup screen, which allows you to configure more options related to the setup of your and 802.11b network devices.

The appearance of the 802.11b Setup screen varies depending on which options are set on the 802.11b Setup screen. The 802.11b Advanced Setup screen for a Hotspot Mode Base Station is shown below.

The 802.11b Hotspot Mode Base Station Advanced Setup screen is used to set up advanced features for an 802.11b Secure Data Mode base station.

Figure 4-38
Hotspot Mode Advanced Setup window
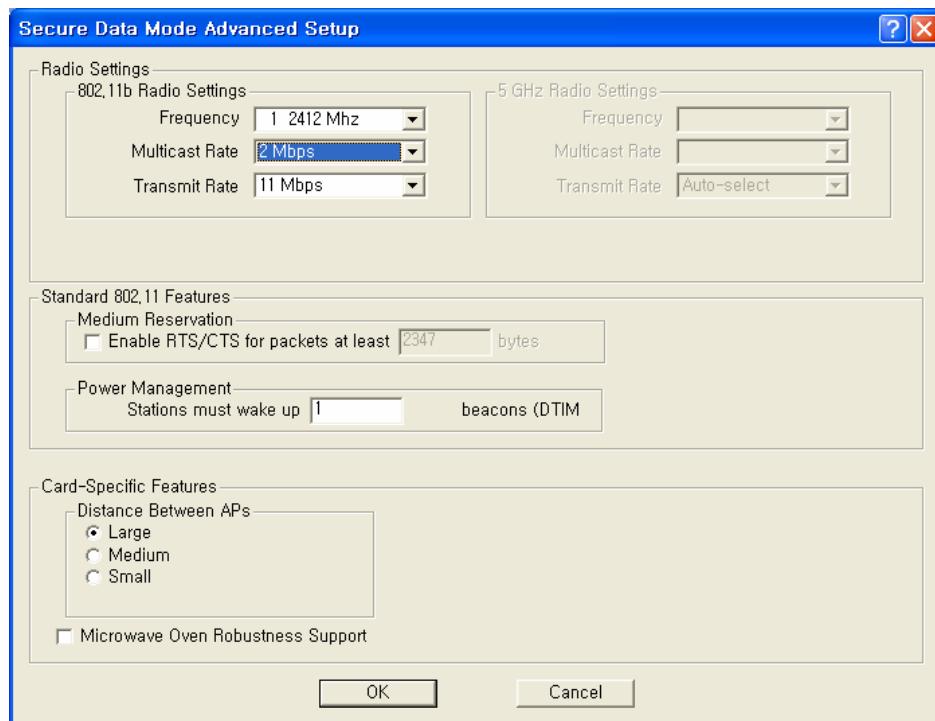

Channel/Frequency-- Select the channel and frequency for the remote device from the drop-down list.   See Frequency Channels for a more detailed explanation of the frequency channels.

Radio Transmit Rate-- Select the radio bit rate used to transmit. Your choices are:

- Auto-select (IEEE 802.11 only)
- Low (1 Mbps)
- Standard (2 Mbps)
- Medium (5.5 Mbps)
- High (11 Mbps)

Multicast Rate-- Select one of the following values:

- 1 Mbit/sec
- 2 Mbits/sec
- 5.5 Mbits/sec
- 11 Mbits/sec

Note that for data communication with wireless clients in its vicinity, the 802.11 device is able to determine the appropriate Transmit Rate for each client individually.

However, for "anonymous data traffic" such as Multicast messages that must be transmitted to all stations simultaneously, the LAN Administrator must identify the correct Multicast Rate.

Warning: Selecting the 5.5 Mbits/sec or 11 Mbits/sec values in network environments that do not satisfy these requirements may result in Multicast messages getting lost.

Enable RTS/CTS - Select this checkbox to enable the Medium Reservation mechanism.

When you enable Medium Reservation, the APU will use the Request to Send/Clear to Send (RTS/CTS) protocol to control wireless data transmissions, based on the length of the data frame that is to be transmitted.

RTS/CTS Threshold-- Enter a Medium Reservation Threshold value. Valid values are any decimal value in the range of 0 to 2347. The default value of 2347 indicates that Medium Reservation is disabled.

Note: Most vendors recommend using a threshold of around 500.

DTIM Period-- The Delivery Traffic Indication Map (DTIM) parameter influences the handling of Multicast messages that need to be transmitted to the wireless medium.
Valid values are any digit in the range of 1 through 65535. The recommended value is 1. Note that the default value of "0" indicates the default used by the manufacturer of the radio card, not "0" milliseconds.

Distance between access points—This selection impacts the multicast rate. ALL stations connected to an AP need to receive broadcasts/ multicasts or some protocols (e.g. IP ARP) will not work. Therefore, the distance between the multiple AP multicasts without negatively impacting performance. The value set (Small, Medium, Large) should be the value that guarantees that all stations will receive the broadcasts.

The following table explains the relationship between these two fields:

Multicast Rate	Then Set Distance Between APs to ...
1 Mbps	Large
2 Mbps	Medium
5.5 Mbps	Medium
11 Mbps	Small

802.11b Security Setup

Clicking the Security button on the 802.11b Setup screen displays the 802,11b Security Setup screen, which allows you to set up security for your 802.11b devices. Note that the fields shown in the screenshot below will vary depending on the version of the Configurator you are using and the options contained in the .bin file. The screen below shows all available options.

Figure 4-39
802.11 Security Setup window
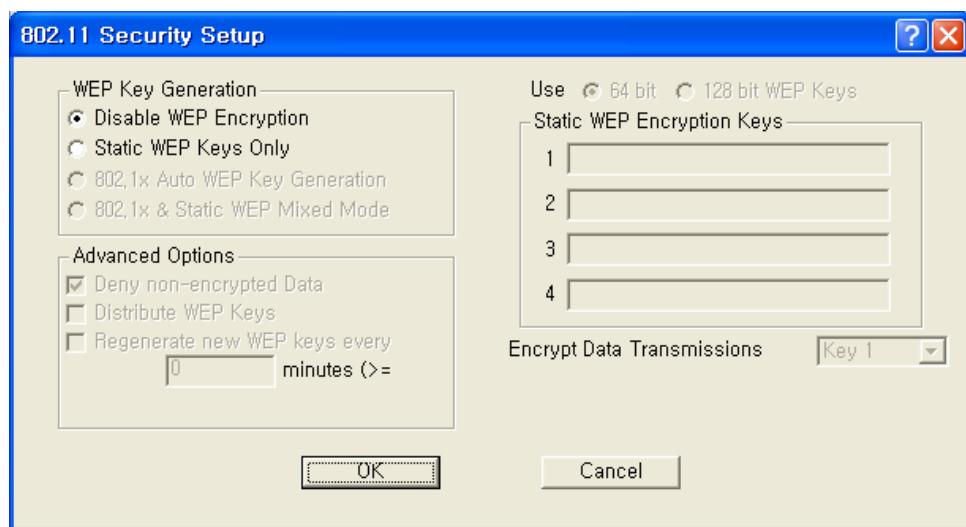

Disable WEP Encryption-- Select this button if you wish to disable Wired Equivalent Privacy (WEP) encryption.
If you are not concerned about security (for example, home users using this device only to browse the Internet), and if you are not concerned your AP is used by others, then select this checkbox.

Note: For simple security, you can disable WEP encryption and select the Closed Wireless System checkbox.

Static WEP Ke**y**s Only-- Select this button if you wish to enter Wired Equivalent Privacy (WEP) keys identically on each access point/station and Secure Data Mode unit in the network. When you select this button, the four Static EP Encryption key fields are enabled on the right side of the screen.

802.1x Auto WEP Key Generation-- Select this option if you wish to automatically create Wired Equivalent Privacy (WEP) keys using the 802.1x protocol. Selecting this option prevents you from creating static WEP keys.

802.1x & Static WEP Mixed Mode-- Select this option if you wish to automatically create Wired Equivalent Privacy (WEP) keys using the 802.1x protocol and also allow static keys.

Deny Non-Encrypted Data-- Select this checkbox if you want to deny all received data that is not encrypted. When this checkbox is selected, any packet received that is not encrypted using one of the four WEP Encryption keys listed above will be dropped. When this checkbox is not selected, unencrypted packets will be accepted and/or forwarded.

Warning: You should always select this checkbox if WEP is enabled in any form. If disabled, clients without WEP can access your network!

Distribute WEP Keys-- If auto key generation is done in any form (auto-only or mixed mode), then the keys must be distributed to the stations. If you have 802.1x enabled on the interface, and STATIC generation ONLY, then the statically defined keys can still be distributed to 802.1x stations. However, if you do not have 802.1x, you cannot distribute WEP keys; and you must use Static keys and enter them manually.

Regenerate New WEP Keys Every n Minutes-- When generating keys, change them every n minutes and send them to the access point/station.

Note: This option is only available for 802.1x devices.

Note: This option only applies if you have selected Auto WEP Key Generation.

Use n-bit WE**P** Keys-- Select either 64-bit (silver) or 128-bit (gold) encryption keys. The higher bit count provides somewhat higher security.

Static WEP Encryption Keys-- If you use static encryption keys, you must enter each key in the Static WEP Encryption Keys fields. Note that these keys must be entered identically on each access point/station and Secure Data Mode unit in the network.

Encrypt Data Transmission Using Key n-- Enter the key number that should be used to encrypt data on this interface. Note that you can receive using any key, but will generally always transmit using a single key. Unicast transmissions to an 802.1x station with dynamic keys will

use that's station's dynamic key, but all broadcasts, multicasts, and other unicasts will be encrypted using the key identified in this field.

Closed Wireless System-- Select this checkbox if you wish to require 802.11 stations to have the 802.11 Service Set Identifier/Network Name entered on their system. Stations without the correct network name will be denied access. Selecting this option indicates that you do not want the AP to broadcast the SSID.   For example, if you select this checkbox, then Windows XP will not be able to see the AP.

Note: For simple security, you can disable WEP encryption and select the Closed Wireless System checkbox. Note, however, the Closed Wireless System checkbox applies only to Orinoco radios.

Configure the APU for Basic MAC Authentication

Advanced Authentication allows you to restrict access to an 802.11 access point by specifying the MAC Addresses of stations that can use the wireless bridge

1. Select the Setup Tab, and then click the General Setup button. The General Setup screen is displayed, as shown below.
2. Select the MAC Authentication Access Control radio button, as shown in the screenshot, then click OK to close the General Setup screen.
3. Click the Advanced Authentication button. The Advanced Authentication Setup screen is displayed, as shown in Figure 4-40.

**Figure 4-40**
General Setup Window
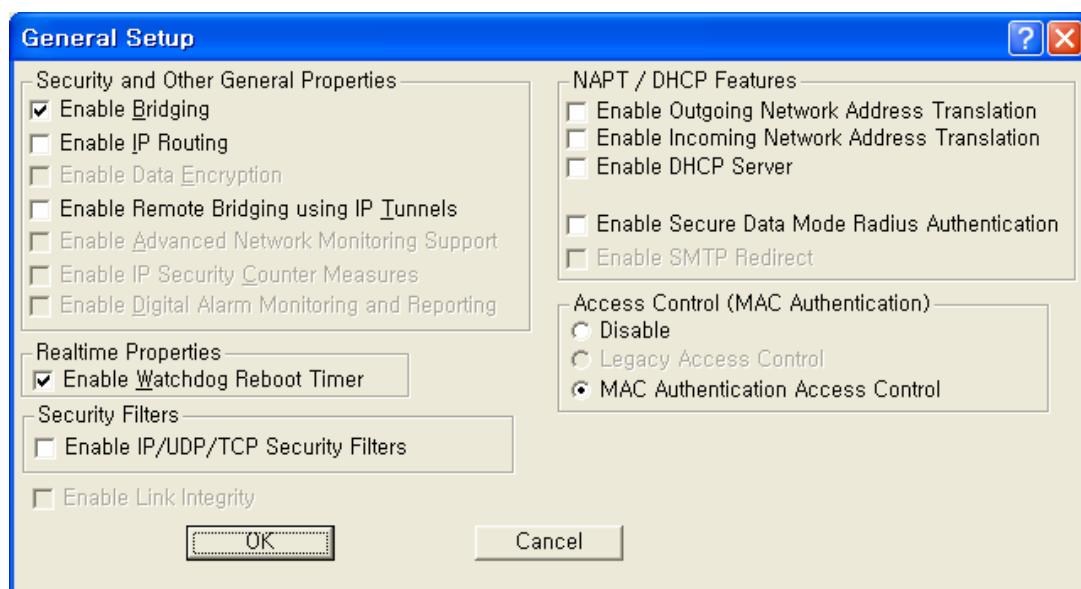

Figure 4-41
Advanced Authentication Setup Window

When a station tries to connect to the hardware device (via Ethernet, 802.11, etc.), the AP can decide whether or not to forward packets to or from that station based on authorization criteria. There are three authentication modules that comprise MAC authentication, but the network administrator determines which of those three modules are used.

- Access Control List (ACL)
- MAC RADIUS Authentication (with optional WARP support)
- 802.1x

These modules are enabled on a per-interface basis. This provides greater control for the network administrator. In essence, the administrator decides whether there will be more or less (or no) authentication on an interface-by-interface basis.
For example, an administrator can permit MAC addresses entered as part of the ACL only on 802.11b, but can permit MAC addresses entered through RADIUS Setup for both the Ethernet and 802.11b interfaces.

The modules are checked in the order in which they appear on the Advanced Authentication Setup screen, and the options that have been selected (checked) determine how authentication is carried out. Assuming that all options are selected, the first method used is the Access Control List, followed by MAC Address Radius, followed by 802.1x authentication. If no options are selected, then no authentication takes place. Zero to three of the modules can be enabled, but at least one module must be enabled for advanced authentication to take place.

The process by which authentication takes place is as follows:

- The first module in the list (for example, ACL) checks the source address of the incoming packet to see if it is permitted to send packets on the selected interfaces.
- The module will designate the address as one of the following:

  - Permit -- the MAC address is permitted on this interface, and packets are forwarded
  - Deny - the MAC address is denied on this interface, and the packets are not sent
  - Unknown - the MAC address is not known on this interface, and is passed to the next authentication module

- If the designation is unknown, then it is passed to the next module in the list (for example, from the ACL to MAC RADIUS Authentication), and the process starts again.

- Ensure that the MAC Address RADIUS Authentication checkbox is enabled, and then click the Setup button. The Authentication Module Setup screen is displayed as shown below.

  Note: The number of tabs displayed on this screen will vary depending on which Advanced Authentication options you have selected on the Advanced Authentication Setup screen. In the screenshot below, all Advanced Authentication options have been enabled.

Figure 4-42
Authentication Module Setup Window
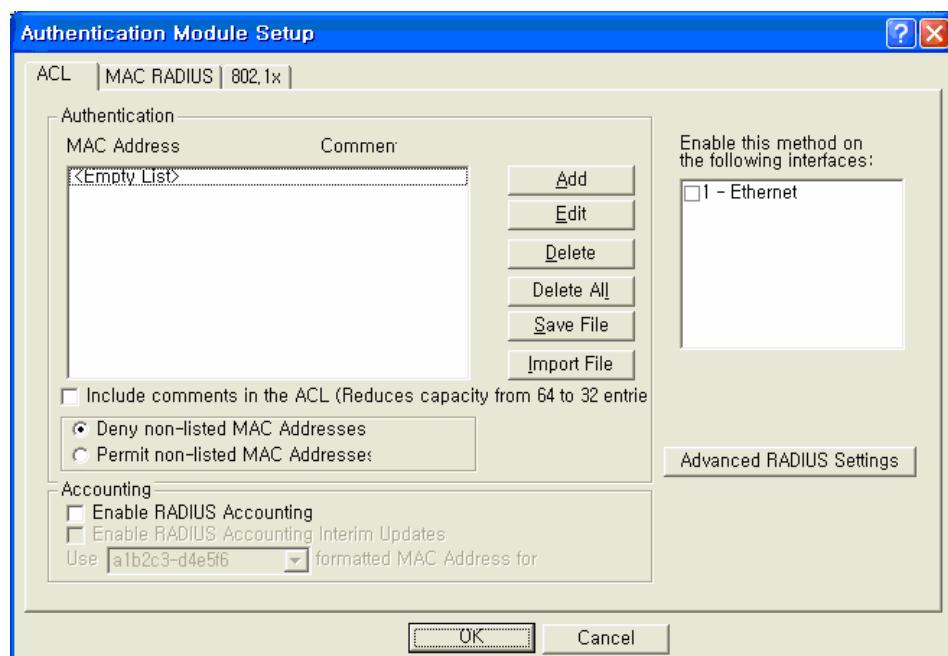

4. Click the MAC RADIUS tab. The MAC RADIUS Setup screen is displayed, as shown below.

Figure 4-43
Authentication Module Setup Windows
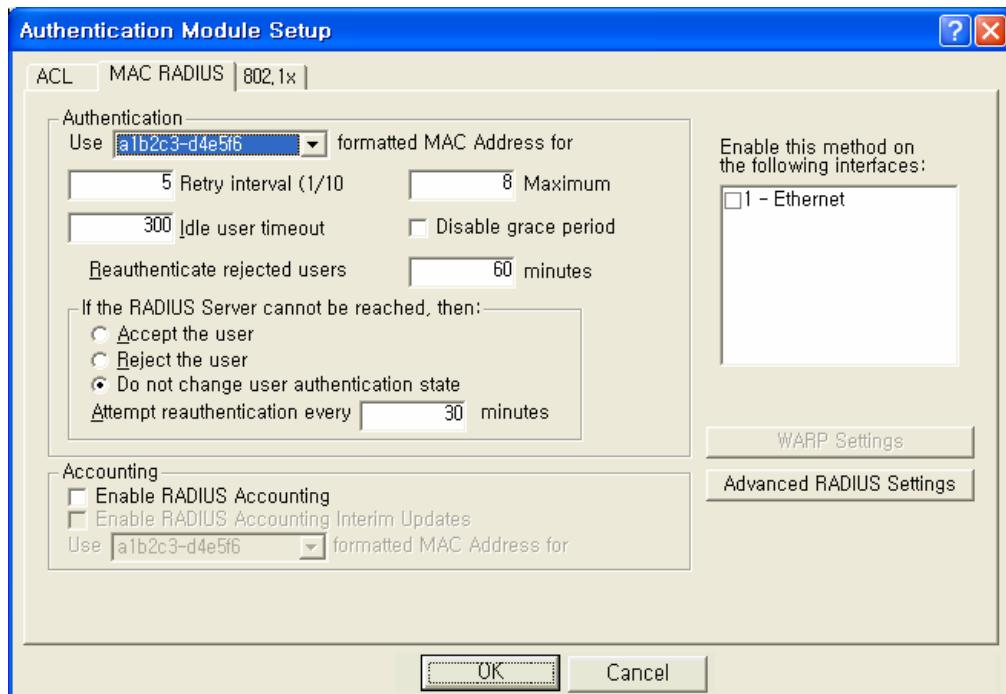

The MAC RADIUS Setup screen is used to define advanced authentication and accounting options for clients that are authenticated via RADIUS using the client's MAC Address as the RADIUS username. RADIUS authentication and accounting server IP addresses and port numbers are set up using the MAC RADIUS Setup screen. Note that this particular MAC RADIUS module applies only to Ethernet and 802.11 access point interfaces.

This screen is used in conjunction with the RADIUS Server Setup screen to define various authentication options. If you wish to use accounting, you must first set up accounting parameters on the RADIUS Server Setup screen.

5. Enter values in the RADIUS Server Setup screen to configure your RADIUS server. Each field on the screen is explained in more detail below.

Use formatted MAC Address for username-- Select "A1-2B-3C-45-CD-EF" if you wish to use all uppercase formatting for MAC address accounting. This format corresponds to the new RFC RADIUS standards.

Select a1b2c3-d4e5f6 if you wish to use the older formatting of MAC addresses. Select EAP packet username if you wish to the EAP packet username(802.1x Authentication only).

Enable this method on the following interfaces.

Select the interfaces used for MAC RADIUS authentication.

Note: You can select either the Ethernet or 802.11b interface if you wish to use WARP.

Retry Interval-- The retry interval for authentication, in tenths of a second. The default value is 5, or a retry interval of .5 seconds. You can set the retry interval to any value between 3 (.3 seconds) and 30 (3 seconds).

Maximum Retries-- The number of times the access point will retry to connect with the server. The default value is 8(eight), and the range for retries is between 1(one) and 10(ten).

Idle User Timeout (sec)
Enter a value in this field if you wish to disconnect users after a period of inactivity. The value entered will be the number of seconds that must pass without activity before users are disconnected.
The default value is 300 seconds (or five minutes). The range of accepted values is between 0 and 3825.

Disable Grace Period -- The grace period allows a client to roam between access points without losing open TCP connections. Select this checkbox if you wish to disable the grace period. If selected, the user does not receive a grace period; if unselected, the user receives a grace period.

Note: The Grace Period must be enabled (unchecked) if you wish to use WARP.

Re-authenticate Rejected Users Every n Minutes -- Select the interval at which users who have not been authenticated will be allowed to re-authenticate. The default interval is 60 minutes.

Accept the User-- Select this radio button if you wish to allow network access to the user if the RADIUS server is down.

Reject the User -- Select this radio button if you wish to deny network access to the user if the RADIUS server is down.

Do not change user authentication state-- Select this checkbox if you wish to keep the user authentication state the same as that before the RADIUS server went down. When this checkbox is selected, if the user was authenticated before the server went down, then the user will remain authenticated. If the user was not authenticated before the RADIUS server went down, then the user will remain unauthenticated.

Note: This field is used in conjunction with the "After n Failed Authentication
Attempts and "Make users wait n seconds" fields.

Attempt Re-authentication Every n Minutes -- If the RADIUS server cannot be reached, the access point will attempt to authenticate all clients via the RADIUS server according to the interval specified here. The re-authentication interval must be specified in increments of 15 minutes. Valid values are 15, 30, 45, etc.

Enable RADIUS Accounting --Select this button if you wish to enable RADIUS accounting. Accounting keeps track of the number of bytes and packets sent by a client. It also keeps track of the amount of time a client has been authenticated. You will want to select this button if you wish to monitor the amount of traffic a client passes, or the amount of time a user is logged on. Typically, you will do this if you wish to bill the client based on time or traffic.

Note: Accounting must be used with authentication. You cannot use accounting without authentication.

Enable RADIUS Accounting Interim Updates -- Select this checkbox if you wish to allow RADIUS accounting updates. If this feature is enabled, the number of bytes and packets sent by a client will be updated according to the update interval defined on the Advanced RADIUS Setup screen.

WARP Settings Button -- Clicking this button displays the WARP Settings screen, which allows you to define various IP addresses and ports that will be used for Wireless Authentication and Registration Protocol (WARP).

Advanced RADIUS Settings Button -- Clicking this button displays the Advanced RADIUS Settings screen, which enables you to define more advanced RADIUS parameters.

Configure the APU for Advanced RADIUS MAC Authentication

1. From the MAC RADIUS Setup screen, click the Advanced RADIUS Settings button. The Advanced RADIUS Setup screen is displayed, as shown below.

Figure 4-44
Advanced RADIUS Setup Window
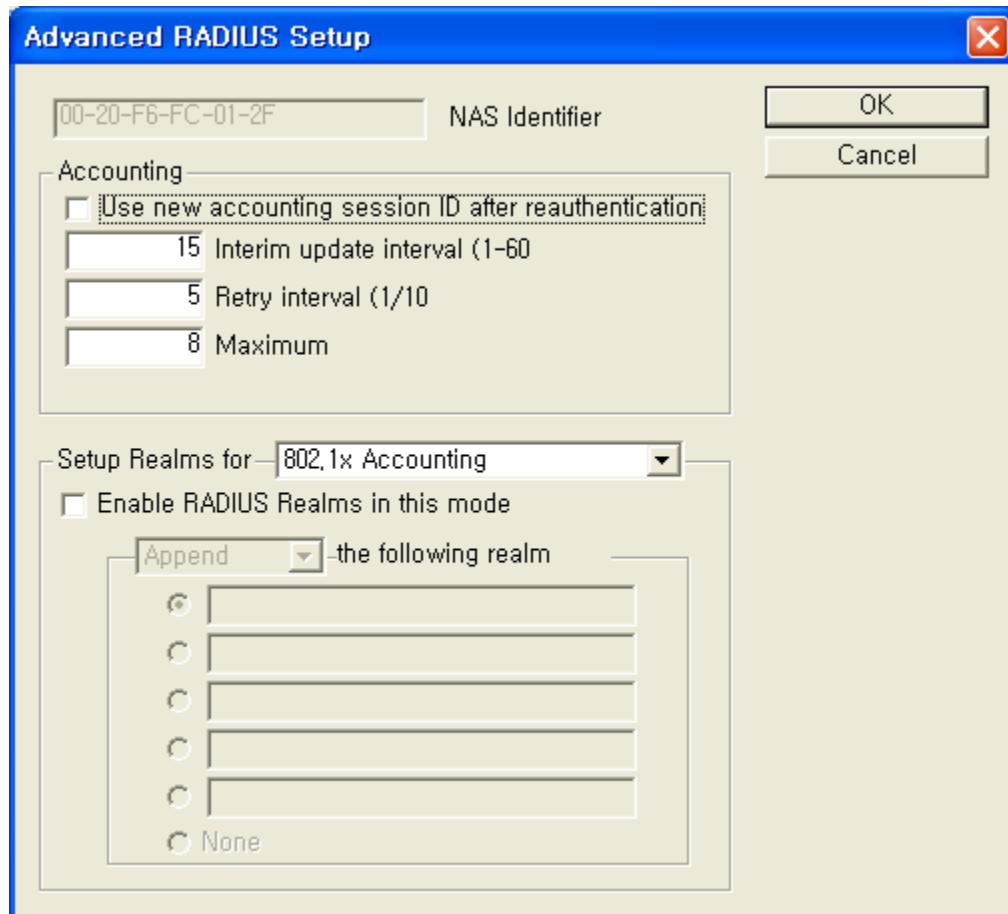

The Advanced RADIUS Setup screen is used to configure optional RADIUS-related parameters.

2. Enter values in the Advanced RADIUS Setup screen, as indicated by the field descriptions below.

NAS Identifier - This field displays your Network Access Server (NAS) name. The access point's SNMP System Name is used as the NAS Identifier, and is shown here for your convenience.

Note: The NAS ID takes the place of the IP address that would normally be used to identify the AP.

Use New Accounting Session ID After Authentication – Select this checkbox if you wish to use another ID for accounting after authentication has taken place.

Interim Update Interval -- Set the interval (in minutes) between interim updates.
The interim update is used to send information in between normal "start/stop" packets. Interim updates are useful because they provide a log of network traffic at a regular interval.

The default value for the interim update interval is 15 minutes. The interim update must be between 1 - 60 minutes.

Retry Interval (1/10 sec) -- The retry interval for accounting, in tenths of a second. The default value is 5 (or a retry interval of .5 seconds). You can set the retry interval to any value between 3 and 30.

Maximum Retries -- The number of times the access point will retry to connect with the server. The default value is 8, and the range for retries is between 1 and 10.

Set Up Realms for **--** When an access client sends user credentials, a user name is often included. Within the user name are two elements:

- Identification of the user account name
- Identification of the user account location

For example, for the user name user1@microsoft.com, user1 is the user account name and microsoft.com is the location of the user account. The identification of the location of the user account is known as a realm.

With RADIUS, a realm is used to separate one name space from another. This allows you to create a login such as user@dom1.com and another login such as user@dom2.com. RADIUS realms also allow Internet Service Providers (ISPs) to segment customer logins, so authentications go to the appropriate RADIUS server(s).

A domain is registered with the InterNIC, and used for mapping servers and services to IP addresses, such as Web, e-mail, etc. Typically, a RADIUS realm corresponds to a domain name (e.g., microsoft.com; yahoo.com). However, there is no requirement to do so, and in fact ISPs often assign realms with no top-level domain (for example, user@dom1 -- without a .com extension).

From the dropdown list, select the accounting or authorization feature for which to provide special handling of <RADIUS realms>. Options currently include:

- 802.1x Accounting
- 802.1x Authorization
- Access Control List (ACL) RADIUS Accounting
- MAC RADIUS Accounting
- MAC RADIUS Authorization

For each of the above Authentication/Accounting types, special handling of RADIUS Realms can be enabled or disabled using the "Enabled RADIUS Realms in this mode" checkbox. Depending on the selected Authentication/Accounting type, different options are available for how to handle RADIUS realms.

Following Realm Name -- Select the type of behavior that will be used for the realm. The behavior determines how the access point handles the realm. Select one of the following realm types:

Append -- Takes the user supplied user name, and appends the realm name onto it (for example, if the user name is smith and the realm name is microsoft.com, then the append action produces smith@microsoft.com)

Supply -- Supplies the selected realm name if the user does not already have one selected. If the user provided a realm name, then use the provided realm name, and do not use the one provided
- Example #1: User provided smith, Behavior is set to Supply, and user did not provide a realm name. The supply action produces jsmith@microsoft.com.
- Example #2: User provided smith, Behavior is set to Supply, and user provided the realm name yahoo.com. The supply action produces jsmith@yahoo.com).

Require -- Requires the user to use the selected realm name (or none, if none is selected). If there is a realm name in the realm name field, the user must have the realm name indicated by the radio button. If the user does not, then he or she is not authenticated. If none is selected, then the user is required not to have a realm name.
- Example #1: User provided smith, Behavior is set to require, user has the realm name microsoft.com, but yahoo.com is entered in the realm name field. The user is not authenticated.
- Example #2: User provided smith, Behavior is set to require, user has the realm name microsoft.com and microsoft.com is entered in the realm name field. The user is authenticated.)

Force -- Replaces any realm name supplied by the user with the selected realm name, or strips off the realm name supplied by the user in the case of none.

- Example: User provided smith, Behavior is set to Force, user provides the realm name microsoft.com, but yahoo.com is entered in the realm name field. The user is authenticated as jsmith@yahoo.com)

Note: The available behaviors vary depending on the type of accounting or authorization realm selected. The following table shows the types of behaviors available for each type of accounting or authorization realm.

Table 4-3

Type of Accounting/Authorization Realm	Behavior(s) Available
802.1x Accounting	• Append
802.1x Authentication	• Append • Supply • Require • Force
ACL Radius Accounting	• Append
MAC RADIUS Accounting	• Append
MAC RADIUS Authentication	• Append

Set Up HotSpot Functionality

You are now ready to set up HotSpot functionality.

1. From the MAC RADIUS Setup screen, click the WARP Settings button. The WARP Settings screen is displayed, as shown below. Enter the HotSpot configuration information on this screen, as explained below.

Figure 4-45
WARP Settings Window
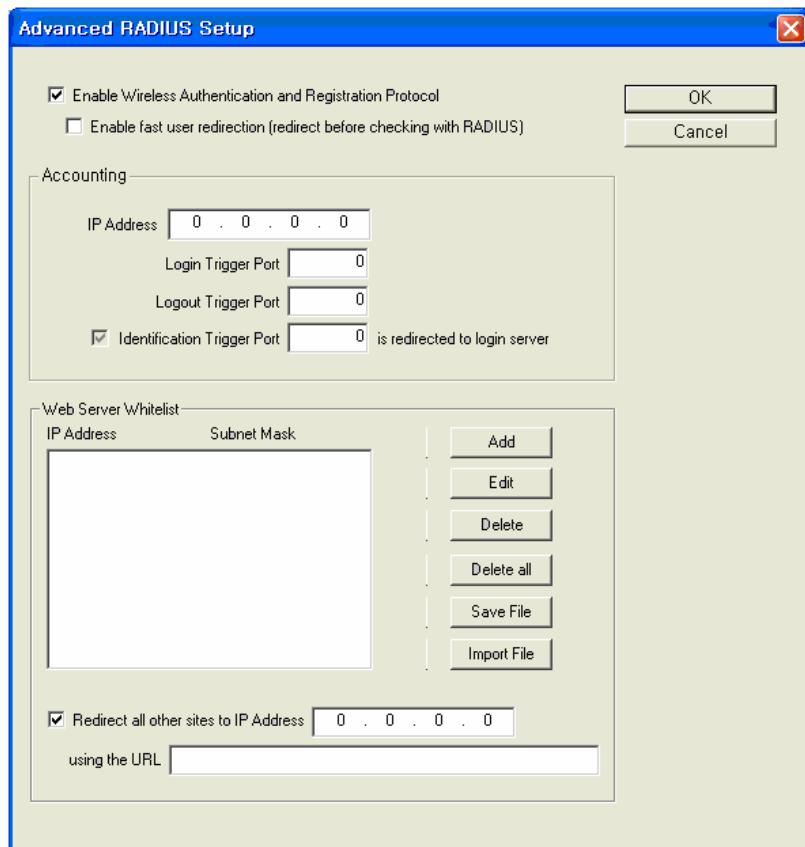

The WARP Settings screen is used to set up parameters for Wireless Authentication and Registration Protocol (WARP).
The WARP feature enables the creation of Hotspots for wireless access. This allows wireless users to access the Internet from their laptops or PDAs, typically on a pay-per-use basis. When WARP is enabled, all traffic is redirected to a login web server, and users will be unable to access other web pages until they have successfully logged in.

Each of the fields and buttons on the WARP Setup screen are explained below.

Enable Wireless Authentication and Registration Protocol -- Select this checkbox to enable the Wireless Authentication and Registration Protocol (WARP) feature. Note that once this checkbox is selected, the other fields on the screen become available.

Enable fast user redirection (redirect before checking with RADIUS) -- Select this checkbox if you wish to provide immediate access to the Internet without going through the RADIUS authentication process.

When enabled, this option redirects all users without consulting the RADIUS server. Users who have an account with time left do not have to repeat the login process. This is particularly useful for roaming, recovery from idle timeouts, and fast Internet access. It is also useful if you wish to show a "splash screen" to all users.

If unselected, users will be redirected to the login server or their home page. The AP is put in a "grace period" and a request is sent to the RADIUS server. Established TCP connections may continue while the request is pending (supports roaming without re-login at each AP). When the response is received, the AP is either redirected to login, or allowed full access to the Internet. Users with time remaining are given a link that bypasses the registration process, and proceed directly to the redirect through the login trigger port. Note that users with no account go through the normal login procedure.

Authentication Web Server IP Address -- Enter the IP address of the web server that should be used for WARP. When WARP is enabled, all traffic will be redirected to this login web server, and users will be unable to access other web pages until they have successfully logged in on a pay-per-use basis.

Authentication Web Server Login Trigger Port -- Enter the number of the port used in conjunction with the IP address of the login web server for WARP. The login server directs successful logins to the trigger port, which makes the access point attempt a second RADIUS authentication. This authentication should be successful because the login updated the RADIUS server client list. The second RADIUS request is done by the access point when it sees traffic to the trigger port.

Note: The login trigger port cannot be the same port as the port used for the login page or the logout trigger port.

Authentication Web Server Logout Trigger Port -- Enter the number of the port used in conjunction with the IP address of the logout web server for WARP. The logout server directs successful logouts to the

trigger port, which attempts a second RADIUS authentication. This authentication should fail because the logout updated the RADIUS server client list. The second RADIUS request is done by the access point when it sees traffic to the logout trigger port.

Note: The logout trigger port cannot be the same port as the port used for the login page or the login trigger port.

Identification Trigger Port n is redirected to Login Server – Enter the port number that the client will be redirected to when the web server needs to obtain the client's identification information. When the Access Point sees the client attempting to connect to the Identification Trigger Port, the client will be redirected to the login server at port 80 and the URL will be filled in with the client's MAC Address by the Access Point.

Note: The Identification URL is independent of the White list URL displayed at the bottom of the WARP Settings screen.

Web Server White list -- The Web Server White list allows you to add or edit IP address/subnet mask pairs that correspond to websites that can be accessed before the user is authenticated. For example, if HotSpot access is being used in a coffee shop, the coffee shop might provide access to its own web site without requiring authentication.

These IP address/subnet mask appear in the Web Server White list window once they have been created.

Clicking the Add button displays the IP Address White list Entry screen, and allows you to add new IP address/subnet mask pairs to your white list.

Selecting an IP address/subnet mask pair in your white list and clicking the Edit button also displays the IP Address White list Entry screen, and allows you to edit one or both of the IP address/subnet mask entries for a particular website.

Selecting an IP address/subnet mask pair in your white list and clicking the Delete button deletes that entry from your white list. You are prompted before the delete occurs.

Clicking the Delete All button deletes every entry in your white list. You are prompted before the delete occurs.

Clicking the Save File button allows you to save the IP address/subnet mask entries in your white list to an external file, which can then be imported at a later time.

Clicking the Import File button displays the standard Windows Open File dialog, and allows you to navigate to the directory where a previously saved white list can be selected and imported into the configurator.

Redirect all other sites to IP Address -- Enter the IP address that will be used to redirect all other sites. The IP address should be associated with the URL entered in the field below.

Using the URL -- Enter the URL (using format http://www.sitename.extension) to which all other sites will be redirected. The URL **must** be associated with an IP address entered in the web server white list or the WARP login server, or the AP will be redirected forever.

If no URL is given, APs will be redirected to "http://<server-IP>/login". This URL is useful to hide the IP, to change the location of the login page, or to redirect to a non-login home page. Note that you must enable the Identification Trigger Port to complete the login process.

Configure the RADIUS Server for Hotspot Service

Once the AP has been configured for basic operation, you are ready to configure the device for HotSpot Mode and Firewall functionality. This is a four-step process:

- Configure the RADIUS Server for Authentication (and, optionally, Accounting)
- Configure the APU for Basic RADIUS MAC Authentication.
- Configure the APU for Advanced RADIUS MAC Authentication.
- Set up HotSpot Functionality

Each step is explained in more detail below. Note that this section assumes that you have launched the AP Configurator and that you have completed all steps in Configure the Access Point for Basic Operation section.

1. From the Setup tab on the Configurator, click the RADIUS Server button. The RADIUS Authentication and Accounting Server Setup screen is displayed, as shown below.

Figure 4-46
RADIUS Setup Window
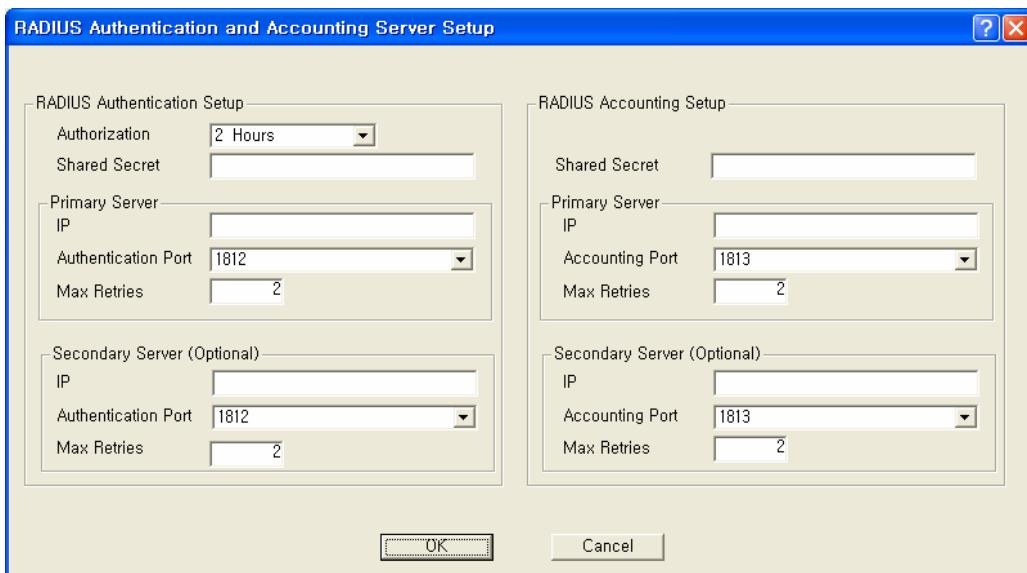

The RADIUS Server Setup screen is used to configure authentication and accounting parameters for terminal servers that speak the RADIUS protocol.
RADIUS is the de-facto standard protocol for authenticating users and for recording accounting information. Accounting keeps tracks of the number of bytes and packets sent by a client. It also keeps track of the amount of time a client has been authenticated. It is commonly used by Terminal Servers or Network Access Servers (NASs) whenever a user logs on and off a dialup Internet service.

Note: This screen is only available if the MAC Authentication Access Control button on the General Setup screen has been selected.

There are two main sections in the RADIUS server setup dialog:

RADIUS Authentication Setup and RADIUS Accounting Setup. In most cases you will want to set up both, although you do not have to set up Accounting. The two are almost identical except for the Authorization Lifetime, which appears only with Authentication.

To set up RADIUS authentication and accounting:

1. Enter values in the RADIUS Authentication and Accounting Server Setup screen to configure your RADIUS server. Each field on the screen is explained in more detail below.

Authorization Lifetime -- Authorization lifetime is the length of time the authorization is valid. Users will need to be-authenticated/re-authorized after this time expires. You should set this value to the maximum time you wish a user to be able to use your service without the need to be re-authenticated.

Shared Secret -- The client file for your RADIUS server contains the IP address and password for the base station you are setting up. You must add the IP address and password (shared secret) from this file in the RADIUS Server Setup screen.

Note: There are separate shared secrets (passwords) for authentication setup and accounting setup. The shared secret is an ASCII string that should be between 2 - 32 characters and should not start with a space.

Primary Server IP Address -- In the RADIUS dialog, enter the IP address for the RADIUS server (the host).

Primary Server Authentication Port -- In the RADIUS dialog, enter the authentication port (default = 1812) for the RADIUS server (the host).

Secondary Server IP Address -- If you are using a second RADIUS server for network robustness, enter the IP address of that RADIUS server.

Primary Server Accounting Port -- In the RADIUS dialog, enter the accounting port (default = 1812) for the RADIUS server (the host).

Secondary Server Authentication Port -- If you are using a second RADIUS server for network robustness, enter the authentication port (default = 1812) for that RADIUS server (the host).

Secondary Server Accounting Port -- If you are using a second RADIUS server for network robustness, enter the accounting port (default = 1812) for that RADIUS server (the host).

Procedure 3-6
Advanced and Optional Configuration

Once you have set up the basic network configuration, you may choose to set up one or more optional or advanced configuration components. This chapter describes how to configure the following optional and advanced components:

Set Up the Bridge

The Bridge Setup screen is used to set up the bridge. In addition, you may use the following screens to set up optional bridge components: The Bridge Setup screen is used to set up the parameters used for bridging. In most cases you will not need to modify the factory configured Bridge Setup. If you are working with an extensive network environment, however, and if you are an experienced network administrator, you may want to modify some of the parameters to fit specific network requirements.

The top half of the screen allows you to define different handling options based on different protocols. The bottom half of the screen allows you to define different handling options based on individual MAC addresses.

Note: This screen is only available when the Enable Bridging checkbox has been selected on the General Setup screen.

Figure 4-47
Bridge Setup window
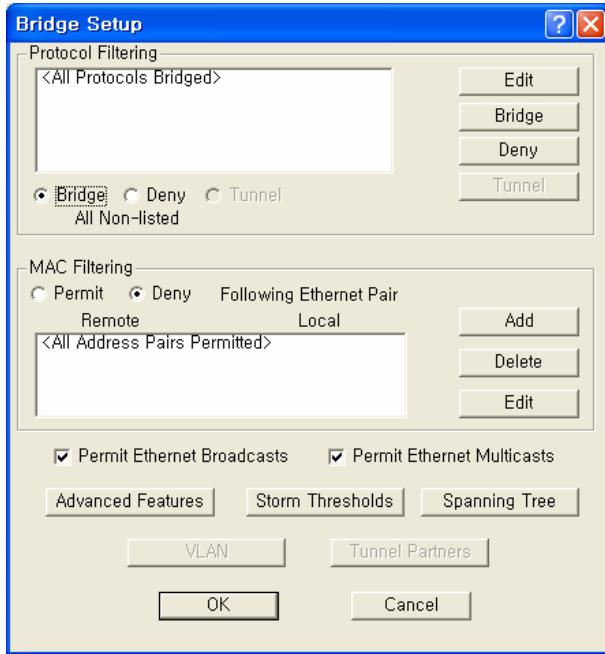

Protocol Filtering

The Protocol Filtering section of the Bridge Setup screen allows you to select a handling method (Bridge, Deny, or Tunnel) for the most common protocols.

Figure 4-48
Protocol Filtering Setup window
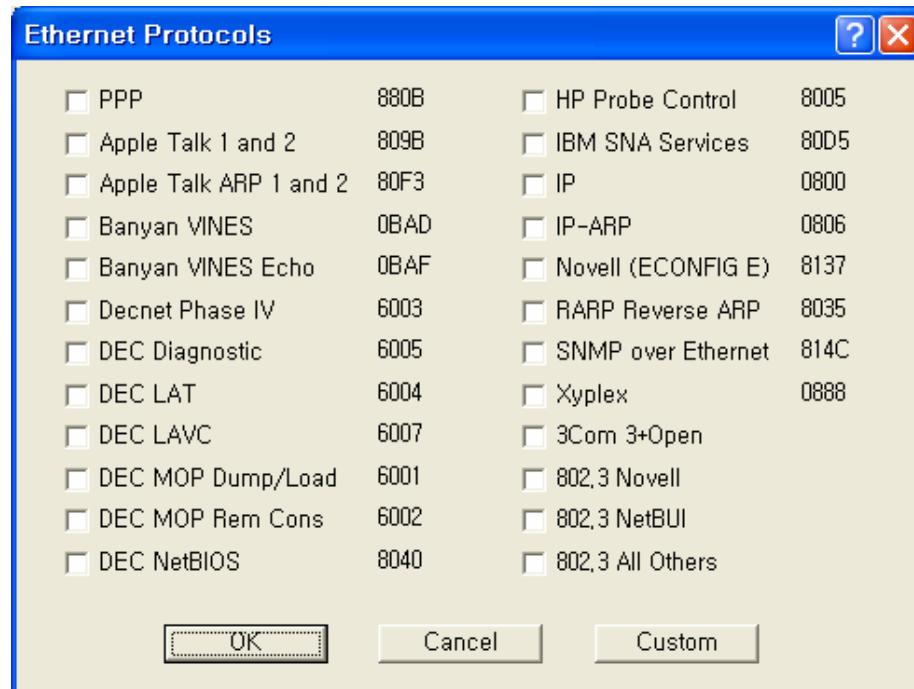

1. Select the protocols from the list that you wish to handle separately, or click the Custom button to add an unlisted protocol. Click the OK button when finished to re-display the Bridge Setup screen. Note that the protocols you have selected are listed in the Protocol Filtering window, and that all protocols are denied by default.
2. If you wish to Bridge or Tunnel any of the protocols in the list, select the protocol, then click either the Bridge or Tunnel buttons
3. At the bottom of the Protocol Filtering list, click the Bridge, Deny, or Tunnel button to define how all other non-listed protocols should be handled.

Note: You can add new protocols to the list at any time by clicking the Edit button and checking additional protocol check boxes.

Tunnel Button--The Tunnel button is used in conjunction with the protocols listed in the Protocol Filtering list. Select a protocol from the list and click the Tunnel button to indicate that the selected protocol should be tunneled.

Deny Button-- the Deny button is used in conjunction with the protocols listed in the Protocol Filtering list. Select a protocol from the list and click the Deny button to indicate that the selected protocol should be denied.

Bridge Button-- the Bridge button is used in conjunction with the protocols listed in the Protocol Filtering list. Select a protocol from the list and click the Bridge button to indicate that the selected protocol should be bridged.

Bridge MAC Address Filtering Overview

You can specify static MAC Address filters in Bridge Setup to optimize the performance and increase security on your wireless (and wired) network. You can permit or deny access to individual stations by specifying their particular MAC Addresses, or to multiple stations by using an X as a wildcard character. You can also permit or deny Ethernet multicast address all traffic that does not match one of the pairs explicitly listed in the Ethernet pair list will be permitted or denied based on your selection.

Table 4-4
Traffic Filtering

Selection	Traffic Matching Listed Pairs	Traffic Not Matching Listed Pairs
Permit Following Ethernet Pair	Permit	Deny
Deny Following Ethernet Pair	Deny	Permit

Stations to be filtered are identified by their MAC Address and whether they are on a remote or local interface. The Interface parameter indicates whether the station with the specified MAC Address is located on the wired or wireless interface of the base station. Use the Add, Delete, and Edit buttons to modify the entries of the list.

Permit Ethernet Broadcasts-- If you wish to deny broadcast traffic in your bridged network, deselect this option. Normally, however, you will select this option to permit Ethernet broadcasts.

Note: This option applies to all Ethernet interfaces, and not simply to Ethernet traffic.

Permit Ethernet Multicasts-- If you wish to deny multicast traffic in your bridged network, deselect this option. Normally, however, you will select this option to permit Ethernet multicasts.

Note: This option applies to all Ethernet interfaces, and not simply to Ethernet traffic.

Advanced Bridging Features

The Advanced Bridge features can be accessed by clicking the Advanced Features button on the Bridge Setup screen.

MAC Layer (Ethernet) Filters allow you to filter Ethernet traffic due to bad or unknown

DHCP Filtering allows you to limit DHCP responses to a particular DHCP server.

IP/ARP Filtering allows you to prevent unnecessary IP/ARP packets from being sent over the wireless link.

Incoming Broadcast Filters allow you to prevent broadcast and multicast packets arriving from the remote interface(s) from being transmitted on the local interface(s).

Outgoing Broadcast Filters allow you to prevent broadcast and multicast packets sent from the local interface(s) from being transmitted out the remote interface(s).
Miscellaneous Statistics Gathering allows you to enable some miscellaneous advanced bridging features.

Figure 4-49
Advanced Bridging Setup window
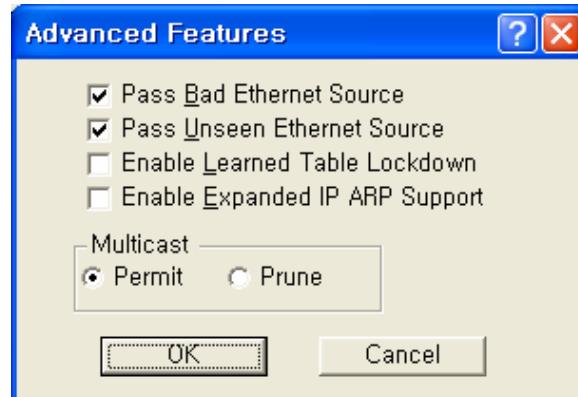

Permit Multicast Button-- Select this checkbox if you wish to permit multicast.

Prune Multicast Button-- Select this checkbox if you wish to prune multicast.

Enable Learned Table Lockdown--A standard Bridge/Router watches the source addresses of each packet it receives on any of its interfaces. As new addresses are seen, entries are added in the "learned table" that contain the particular source address and the interface number that address was received on. If that source address is later seen on a different interface, the Bridge will immediately change the interface number in the learned entry table. This condition could happen in a correctly functioning network if someone moved the computer to a different part of the network.
 This could also happen if someone was trying to capture network packets by spoofing the Bridge. Enabling learned table lockdown will prevent the interface number from being changed once the source address has been seen.

A standard Bridge will also time-out the learned table records every ten (10) minutes. If learned table lockdown is enabled, these records will not be timed-out. Once a record is learned, it will not be changed or deleted until either the Secure Data Mode station reboots or the learned table becomes completely filled and needs to be reset.

Note: A typical Secure Data Mode learned table can contain over 12,000 records.

Enable Expanded IP/ARP Support

Enabling this feature will cause the Secure Data Mode station to watch the IP/ARP packets that occur on the network. Normally, no action is taken in response to an IP/ARP packet that is not destined for a host that is being Proxy ARPed by the Secure Data Mode station. When this function is selected, the Secure Data Mode station will add the IP address to its IP/ARP table when it sees an ARP packet from another source. This feature is helpful on an ARP network because it will build a database of MAC layer address to IP address pairs.

Note: The IP/ARP table is never timed out in this mode.

Storm Threshold Setup

The Storm Thresholds screen is used to set threshold values for broadcast and multicast messages.

In most situations, you will not need to set the Storm Thresholds. However, if intensive multicast or broadcast messaging is typical of the network protocols used in your network environment, you may wish to control the maximum number of broadcast and multicast messages. If the maximum value of broadcast or multicasts per second is exceeded, the Secure Data Mode Station will ignore all subsequent messages issued by the particular network device, or ignore all messages of that type coming on that particular interface.

You can use the Storm Threshold screen to:

- Specify a maximum value as received from a single network device (identified by its MAC address).
- Specify an absolute maximum of messages per second per Interface.

You can specify a set of thresholds for each Interface of the Secure Data Mode Station access point, identifying separate values for the number of Broadcast messages/second and Multicast messages/second.

Figure 4-50
Broadcast Storm Setup window
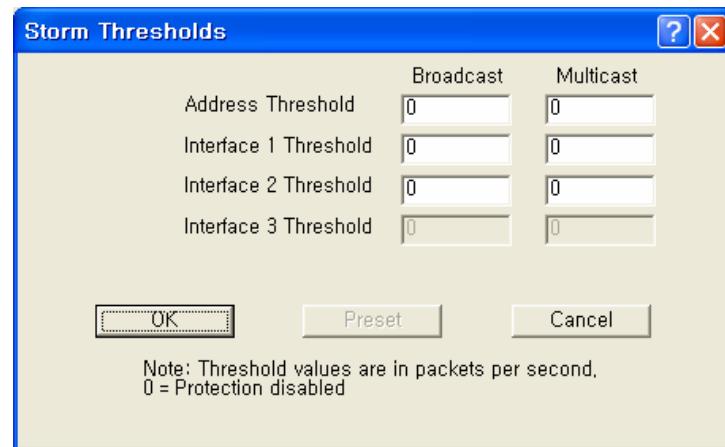

Broadcast Address Threshold

Enter the maximum number of broadcast messages per second that will be received from a single network device (identified by its MAC address).

Multicast Address Threshold-- Enter the maximum number of multicast messages per second that will be received from a single network device (identified by its MAC address).

Broadcast Interface 1 Threshold-- Enter the maximum number of broadcast messages per second that will be received on Interface 1 (typically Ethernet).

Multicast Interface 1 Threshold-- Enter the maximum number of multicast messages per second that will be received on Interface 1 (typically Ethernet).

Broadcast Interface 2 Threshold-- Enter the maximum number of broadcast messages per second that will be received on Interface 2 (typically 802.11b).

Multicast Interface 2 Threshold-- Enter the maximum number of multicast messages per second that will be received on Interface 2 (typically 802.11b).

Broadcast Interface 3 Threshold-- Enter the maximum number of broadcast messages per second that will be received on Interface 3 (typically 802.11a).

Multicast Interface 3 Threshold-- Enter the maximum number of multicast messages per second that will be received on Interface 3.

P**res**et Button-- Clicking the Present button sets all broadcast and multicast rates to their default values. The default values are as follows:

Table 4-5
Default Threshold values

Item	Broadcast	Multicast
Address Threshold	30	30
Interface1 Threshold	60	60
Interface2 Threshold	60	60
Interface3 Threshold	60	60

Spanning Tree Setup

The Spanning Tree Setup screen allows you to configure your bridges so that they will dynamically discover a loop-free subset of the LAN topology (a tree), that provides the most efficient level of connectivity between every pair of physically connected Local Area Network segments. See Spanning Tree for more information about how the spanning tree algorithm works. The default settings for the Spanning

Tree Algorithm will provide satisfactory performance for most Local Area Network (LAN) topologies.

Enable Spanning Tree-- Select this checkbox if you wish to enable Spanning Tree capabilities.

Figure 4-51
VLAN Spanning Tree Setup window
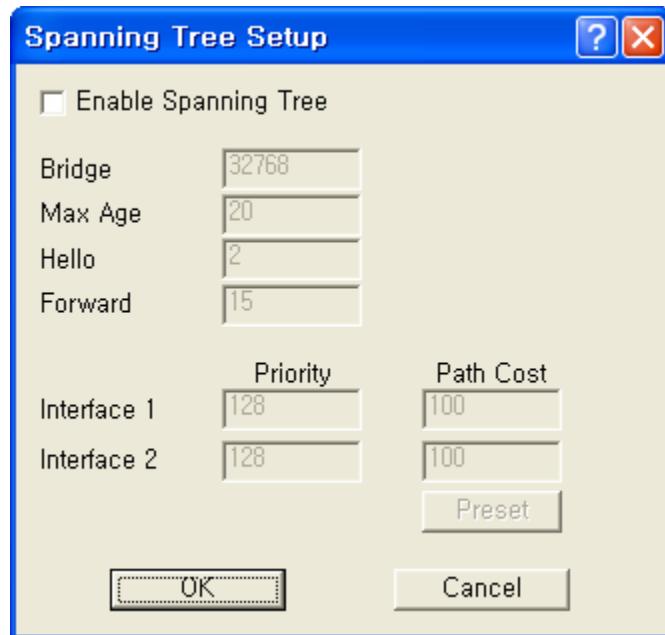

Bridge Priority-- The Bridge Priority parameter allows you to influence the choice of the Root Bridge and Designated Bridge as calculated by the Spanning Tree Algorithm.

Valid Values: 0 - 65000
Default: 32768

A low numerical value makes the bridge more likely to become the designated bridge or root bridge (typically 0).
The recommended value is 32768.

You may assign a duplicate priority value to multiple bridges, provided that it is a non-zero value. Bridges that have an identical Bridge Priority level are typically not intended to function as the root bridge.

Max Age-- The Max Age parameter identifies the maximum age of received Spanning Tree protocol information.

When the bridge receives protocol information that exceeds the Max Age value, the bridge will discard the information and start the Forward Delay timer to allow other bridges to forward updated topology information (for example, that another bridge has become the Root Bridge).

Note: Recommended Value (20 seconds)

A low Max Age value occasionally may cause the Spanning Tree to reconfigure unnecessarily, resulting in temporary loss of connectivity throughout the network.
A high Max Age value will cause the LAN to take longer than necessary to rebuild the Spanning Tree whenever a link or bridge unit breaks down or becomes available again.

Hello Time-- The Spanning Tree Hello Time parameter identifies the time interval between Configuration PBDU transmitted by a root bridge, or a bridge that is attempting to become the root bridge.

Note: Recommended Value (2 seconds)

Shortening the Hello Time will make the protocol more robust, especially when the probability of loss of configuration messages is high.

Lengthening the Hello Time will lower the overhead of the algorithm since the interval between the transmissions of configuration messages will be longer.

Forward -- The Forward Delay is a timer that prevents a bridge to forward data packets when:
- The bridge receives information that the active Spanning Tree topology must be updated (for example when a bridge breaks down or when somebody modified the Bridge Priority or Path Cost value of a particular bridge).
- The bridge registers that the protocol information exceeds the specified Max Age value.
- Changes in the Spanning Tree topology must be communicated to all bridges in the bridged network. The Forward Delay timer will compensate for the propagation delays that occur in passing the protocol information, allowing all bridges to close the old data paths, before the new data paths are activated.

Note: Recommended Value (15 seconds)

A lower value may result in temporary loops as the Spanning Tree Algorithm converges.

A higher value may result in longer partitions after the Spanning Tree reconfigures.

Port Priority-- Normally the Bridge Port priority in Spanning Tree topologies is imposed by the Root Bridge and the applicable values of the Path Cost to the Root Bridge.
When concurrent bridge ports of a single bridge unit are connected in a loop, this parameter enables you to influence which port should be included in the Spanning Tree.

Valid Values: 0 - 255
Default: 128

A lower value makes a port more likely to become selected in the Spanning Tree than the concurrent one that has a higher numerical value. A higher value makes a port less likely to be selected in the Spanning Tree than a port with a lower numerical value.

Path Cost-- The Path Cost value is used to determine the preferred data paths between bridges throughout the network and the root bridge.
The Root Bridge transmits BPDU messages throughout the Local Area Network. When a bridge unit receives a BPDU message at one of its ports, it will add the value in the Path Cost field for that port to the value in the Root Path Cost Field of the BPDU message before forwarding the message again. This will help the other bridges to determine the Total Path Cost to the Root Bridge via this port.

Valid Values: 0 - 255
Default: 100

A lower Path Cost value would typically be used for ports to LAN segments closer to the Root Bridge.
A higher Path Cost value would typically be used for ports to LAN segments that are the "leafs" of the Spanning Tree.
For example, when using the Secure Data Mode Station as an access point for wireless stations to the Ethernet, a high Path Cost for the wireless interface will minimize unnecessary use of the bandwidth for the wireless medium (recommended value 255).
When using Secure Data Mode Stations in a wireless point-to-point link to interconnect two LAN segments, a low Path Cost for the wireless interface will prioritize this link as compared to other physical links, such as a leased line or low-bandwidth connections.

Set Up IP for APU and CSU

The IP Setup screen allows you to set the Secure Data Mode Station's IP Addressing information. The Secure Data Mode Station must have an IP address assigned to it if you wish to connect to it using the Configuration tool, which makes use of SNMP to connect to the Secure Data Mode Station.

Note: This screen is only available when the Enable IP Routing, Enable Outgoing Network Address Translation, and Enable Incoming Network Address Translation checkboxes been de-selected on the General Setup screen.

Figure 4-52
IP Setup window
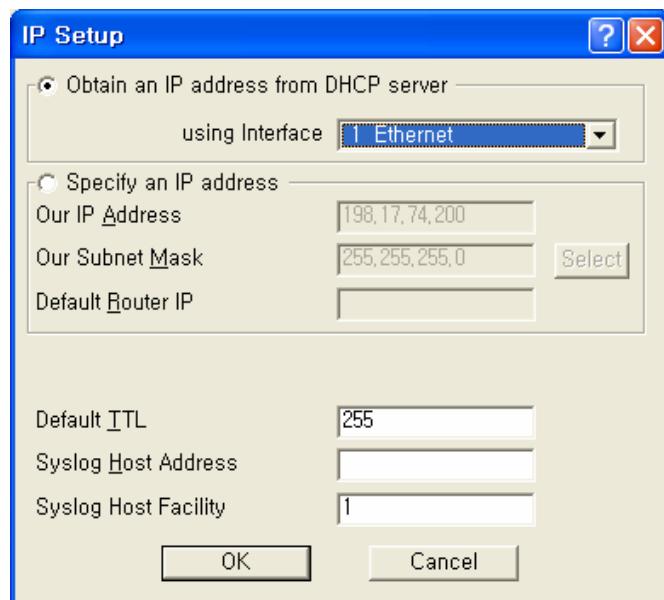

You can choose to set up the base station to obtain an IP address from DHCP server. If you select this option, you must also choose the interface on which you would like the base station to send the request. This option causes your base station to send a broadcast request for its IP address, subnet mask, and default router over the given interface at base station startup time. If you select the DHCP option, it is recommended (though not required) that you set up your DHCP server to always provide the same IP address to this Secure Data Mode Station system.

You can also manually specify an IP Address to set the IP Address for the base station yourself:

132

You can set the life expectancy for packets originating from this Secure Data Mode Station using the Default TTL (Time to Live) field.

You can use syslog messages to log information such as logins, service errors and general configuration information. Since there is no storage on a base station, a general purpose computer is needed to log these messages. To set the syslog host that will accept syslog messages, use the Syslog Host Address and Syslog Host Facility fields.

Obtain an IP Address from DHCP Server-- Select this radio button if you wish to obtain an IP address from the DHCP Server.

If you select this option, you must also choose the interface on which you would like the base station to send the request. This option causes your base station to send a broadcast request

For its IP address, subnet mask, and default router over the given interface at base station startup time. If you select the DHCP option, it is recommended (though not required) that you set up your DHCP server to always provide the same IP address to this Secure Data Mode Station system.

Using Interfaces-- Select the interface for which you wish to obtain an IP address. A base station has several network interfaces to which it may be connected. The network interfaces are numbered (1, 2, 3...), and the interface numbers may be found by selecting Interface Setup from the Setup Menu.

Specify an IP Address-- Select this radio button if you wish to enter an IP address manually.

Our IP Address-- This is the address of the Secure Data Mode Bridge/Router itself. If you wish to configure or monitor your Secure Data Mode Bridge/Router, or if your network supports IP and you wish to enable the Ping support and IP/SNMP support of the Secure Data Mode Bridge/Router, set this to a valid IP address. After setting this address to 0.0.0.0, enter the IP address of the base station.
Please note that unless you enable IP Routing on the IP Router Setup screen, the Bridge/Router is not an IP router. It has only one IP address, and that address applies to both the remote and local networks (i.e., both sides of the Bridge). Having two Ethernet interfaces with the same IP address is different than a standard IP host, but is appropriate for a Transparent Bridge. The Ethernet address of both interfaces is also the same.

Note: This field is only enabled when the Specify an IP Address radio button has been selected.

Our Subnet Mask-- Enter the subnet mask for the base station.

Note: This field is only enabled when the Specify an IP Address radio button has been selected.

Default Router IP-- Enter the IP address of the router.

Note: This field is only enabled when the Specify an IP Address radio button has been selected.

Select Button-- Clicking this button displays the IP Mask List screen, which allows you to select a particular IP mask.

IP Mask List-- The IP Mask List window displays a list of common IP subnet masks for a given size IP subnet.

Default TTL-- The Time To Live (TTL) counter avoids endless forwarding of message frames with incorrect addressing by defining a maximum number of hops a packet can take. Each time the frame is forwarded by a router, the TTL counter decreases by one.
When the TTL = 0, the frame is rejected.

Syslog Host Address-- Syslog messages can be used to log information such as logins, service errors and general configuration information. Since there is no storage on a base station, a general purpose computer is needed to log these messages.
The Syslog Host Address is the IP Address of the system which accepts "syslog" system logging packets from the base station.

Syslog Host Facility

Syslog messages can be used to log information such as logins, service errors and general configuration information. Since there is no storage on a base station, a general purpose computer is needed to log these messages.
The Syslog Host Facility describes the part of the system generating the syslog message, and in UNIX-based systems usually uses one of the following keywords: auth, authpriv, cron, daemon, kern, lpr, mail, mark, news, syslog, user, uucp, and local0 through local7.
The base station is capable of sending messages using the local0-local7 facilities. Enter the correct syslog facility number (0-7) that corresponds to the local facility type on your syslog host.

Set Up SNMP

The SNMP Setup screen allows you to manage a network environment that includes multiple base stations where you can use the Simple Network Management Protocol (SNMP).
SNMP setup allows you to create multiple authorization levels for network management that are password protected.

Figure 4-53
SNMP Setup window
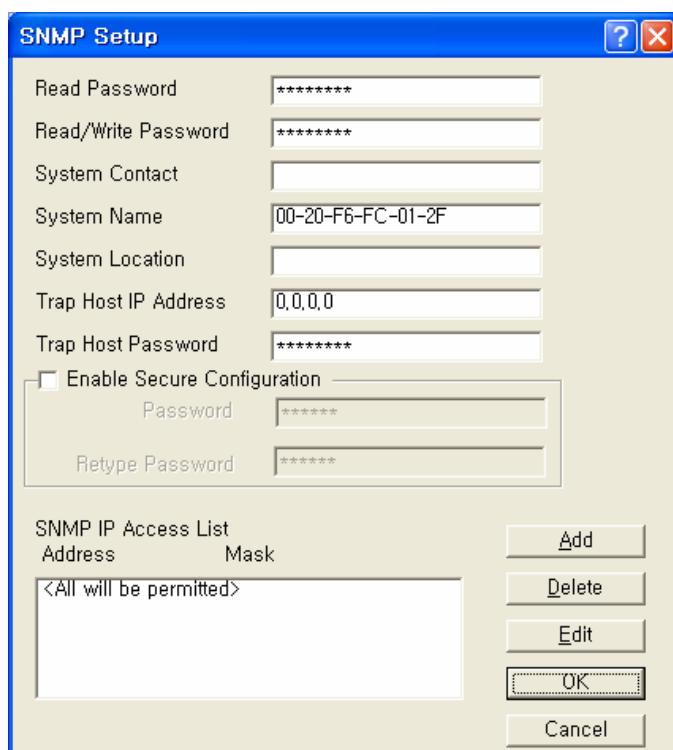

Read Password-- This password enables you to create a network management level where a local LAN Administrator can view, but not modify, the SNMP parameters.

Read/Write Password -- This password enables you to create a network management level where only a Network Supervisor knowing the right Read/Write password will be able to view or modify the SNMP parameters.

Contact--Optionally, enter the name or address of the Network Administrator.

System Name-- Optionally, enter the logical location of a base station (for example, the network segment to which the base station has been connected).

System Location-- The optional field to identify the physical location of a base station. For example, the building or room where the base station is located at

Trap Host IP Address-- The IP Address of the network management station that collects the SNMP Trap messages.

The Trap Host is the station in an SNMP managed network where SNMP trap messages are collected. Trap messages are sent to the trap host when certain events occur, such as rebooting.

Trap Host Password-- The Trap Host is the station in a SNMP managed network where SNMP trap messages are collected. Trap messages are sent to the trap host when certain events occur, such as rebooting.

Enter a password that corresponds to the password set at the Trap Host to filter unsolicited or unauthorized SNMP Trap messages at the Trap Host.

The Trap Host IP Password will be embedded in the SNMP Trap messages sent by this base station. If the Trap Host receives a message without or with an unknown password, the Trap message will be ignored.

SNMP IP Access List-- The SNMP IP Access List displays the IP addresses and subnet masks of those stations that you have designated as stations that will manage networks using SNMP.

In addition to the Read and Read/Write passwords, you can use the SNMP Access List to prevent unauthorized users from modifying the SNMP setup of your base stations.

The SNMP IP Access List enables you to authorize SNMP management to a restricted group of SNMP Management stations identified by:

- The unique IP address of the Management Station(s)
- The interfaces via which the base station will be accessed.

Click the Add button to display the Input SNMP Access List to add new IP addresses to the list.

Input SNMP Access List Dialog - Overview

Clicking the Add button displays the SNMP Access List Dialog, which allows you to enter the IP addresses and subnet masks of those stations that you have designated as stations that will manage networks using SNMP.

Figure 4-54
Input SNMP Setup window
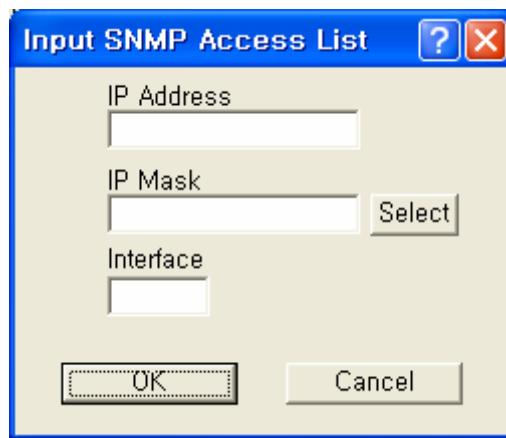

IP Address-- The unique IP address of the SNMP management station you wish to add or edit.

IP Mask-- Enter the Subnet mask, or clicks the Select button to display the IP Mask List and select a mask from the list.

Note: A subnet mask value of 255.255.255.255 will authorize only the station with the address specified in the IP address. A subnet mask value of 255.255.255.0 will authorize all stations that have an IP address within the range of that particular subnet (the IP address field will display the value xxx.xxx.xxx.0).

Warning: The subnet mask value 0.0.0.0 will authorize any station to view or modify SNMP IP setup of the base station via the interface identified in the Interface field.

Interface-- The number of the interfaces over which packets on this route is sent.

Select Button-- Clicking this button displays the IP Mask List screen, which allows you to select a particular IP mask.

Set Up IP Routing

The IP Router Setup screen is used to set up IP Routing. This enables the base station to send IP packets to the appropriate subnet or router. Once you have set up the basic IP Router configuration, you may also want to set up the following optional components:

Note: This option is only available if the Enable IP Routing checkbox on the General Setup screen has been selected.

Figure 4-55
IP Router Setup window
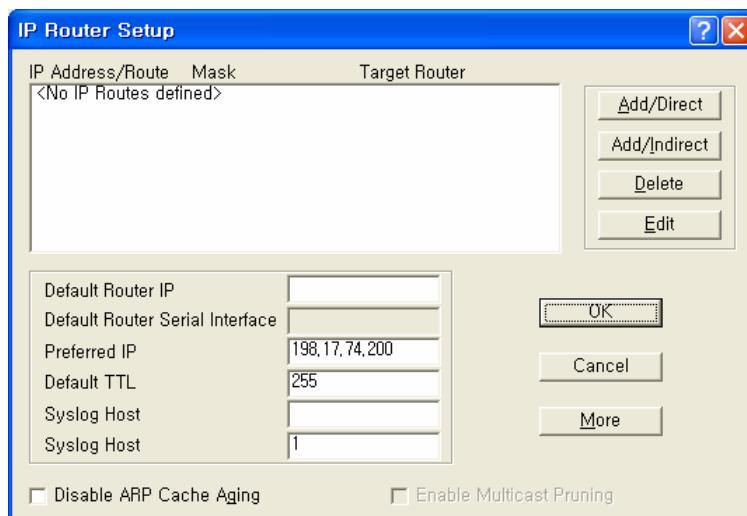

IP Route List

This pane displays the list of IP Routes that this Router has been configured to use. To add additional direct or indirect routes, click on the Add/Direct or Add/Indirect buttons.

Table 4-6
IP Route List

IP Route List	This pane displays the list of IP Routes that this Router has been configured to use. To add additional direct or indirect routes, click on the Add/Direct or Add/Indirect buttons.
Mask	The Subnet Mask of the IP Address, which shows which addresses should be routed using this route.
Target	For a Direct Route, the word Direct appears in this field. For an Indirect Route, this field shows the Default Router.
Interface/Cost	For direct routes, the interface to use when sending packets using this route. For indirect routes, the cost metric of using this route (used to determine the best route to use for a given packet).

Default Router IP Address-- Enter the IP Address of the router that the base station should use to communicate with networked devices outside its current subnet.

Default Router Serial Interface-- The Secure Data Mode station has several network interfaces to which it may be connected. An interface number is required for the Secure Data Mode station to know which interface to use to send packets addressed to a given destination. This field displays the serial interface that the router will use by default.

Preferred IP Address-- From time to time, the Secure Data Mode Bridge/Router will transmit unsolicited IP packets such as SNMP traps, Syslog, RIP, or IP/ARP packets. Most routers randomly use one of the IP addresses from one of the router interfaces as the source IP address for these packets. However, in the Preferred IP Address field, you can specify the source IP address that you prefer to use for these packets.

Default TTL-- The Time To Live (TTL) counter avoids endless forwarding of message frames with incorrect addressing by defining a maximum number of hops a packet can take. Each time the frame is forwarded by a router, the TTL counter decreases by one. When the TTL = 0, the frame is rejected.

Syslog Host Address-- Syslog messages can be used to log information such as logins, service errors and general configuration information. Since there is no storage on a base station, a general purpose computer is needed to log these messages.

The Syslog Host Address is the IP Address of the system that accepts "syslog" system logging packets from the base station.

Syslog Host Facility-- Syslog messages can be used to log information such as logins, service errors and general configuration information. Since there is no storage on a base station, a general purpose computer is needed to log these messages.
The Syslog Host Facility describes the part of the system generating the syslog message, and in UNIX-based systems usually uses one of the following keywords: auth, authpriv, cron, daemon, kern, lpr, mail, mark, news, syslog, user, uucp, and local0 through local7.

The base station is capable of sending messages using the local0-local7 facilities. Enter the correct syslog facility number (0-7) that corresponds to the local facility type on your syslog host.

Disable ARP Cache Aging-- Select this checkbox to stop the Address Resolution Protocol (ARP) table from removing entries after a certain

period of time. The IP ARP table relates each (wired or wireless) station's IP address to its physical MAC Address so the base station knows how to address Ethernet messages bound for a particular IP Address. If you disable (uncheck) ARP cache aging, the base station will not remove entries from this table, and it may fill up over time. The base station can hold up to 10,000 entries in the ARP table.

Enable Multicast Pruning-- Select this checkbox if you want to enable multicast pruning.

IP multicast is a bandwidth-conserving technology that reduces traffic by simultaneously delivering a single stream of information to potentially thousands of corporate recipients and homes.
Without multicast pruning, multicast traffic is treated in the same manner as broadcast traffic. That is, it is forwarded to all ports. However, with multicast pruning, you choose to permit only the packets that are a part of multicast group in your network. Multicast pruning generates no additional network traffic, allowing you to significantly reduce multicast traffic passing through your switch.

Add Direct IP Routes

Clicking the Add/Direct button displays the Add Direct IP Route screen, which allows you to add new direct IP routes.
When the Secure Data Mode station has two or more IP subnets directly attached to its different interfaces, it can route IP packets between those subnets using a direct route. This screen is used to specify the direct routes for each of the interfaces on the Secure Data Mode Bridge/Router. A direct route consists of an IP address, which specifies the basic IP address to route, a Subnet Mask which defines the basic class of IP addresses that will be routed, and an interface number which specifies where the IP subnet is attached. When IP packets addressed to a system arrives at the Secure Data Mode station, the Secure Data Mode station will send it directly to the target machine on the interface specified.

Figure 4-56
Direct IP Route Setup window
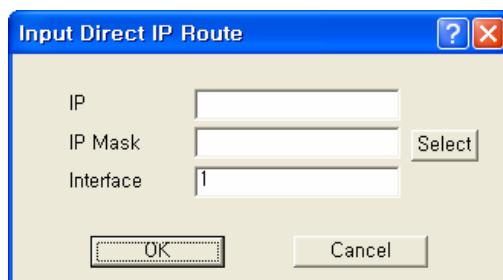

IP Address-- The IP address specifies the basic IP address to route.

IP Mask-- The Subnet Mask which defines the basic class of IP addresses that will be routed. Clicking the Select button displays the IP Mask List, which the shows the IP Masks that can be used as public or private IP masks for IP routing. The list consists of all possible subnet masks, and represents the range of addresses that will be translated.

Interface-- An interface number specifies where the IP subnet is attached.

Add Indirect IP Routes

The Add Indirect IP Route screen is used to add indirect IP routes.

When the base station needs to send IP packets between IP subnets which are not directly connected to one of its interfaces (i.e., not on the same network segment), it must have an indirect route for sending those packets.

An indirect route consists of:

- An IP Address which specifies the basic IP address to route,
- A Subnet Mask which defines the class of IP addresses that will be routed,
- A Target Router that will relay the IP packet, and
- A Cost value, which specifies the number of "hops" required for the indirect route.

When an IP packet addressed to a system on the indirectly routed subnet arrives at the base station, the base station will route it over the interface specified to the Target Router to be further routed.

Figure 4-57
Indirect IP Route Setup window

IP Address-- The IP Address which specifies the basic IP address to route.

IP Mask**--** Enter the IP subnet mask for the IP address to be routed, or click the Select button and choose a subnet mask from the list. Clicking the Select button displays the IP Mask List, which the shows the IP Masks that can be used as public or private IP masks for IP routing. The list consists of all possible subnet masks, and represents the range of addresses that will be translated.

Target Router-- Enter the IP address of the router that you wish to use as the target router.

A target router is the IP address of the router that knows how to handle the IP packet that is being routed. When used in indirect routes, it could specify the router that is attached directly to the subnet of the packet's final destination, or a router that knows where to send it.

Cost-- The cost value reflects the number of "hops" required for the connection.   The default value of 1 indicates that only one "hop" is required. The lower the cost value, the more likely that route will be chosen.

Advanced IP Routing Setup

The More IP Router Setup screen is used to set up advanced IP router interfaces.

Figure 4-58
Advanced IP Routing Setup window
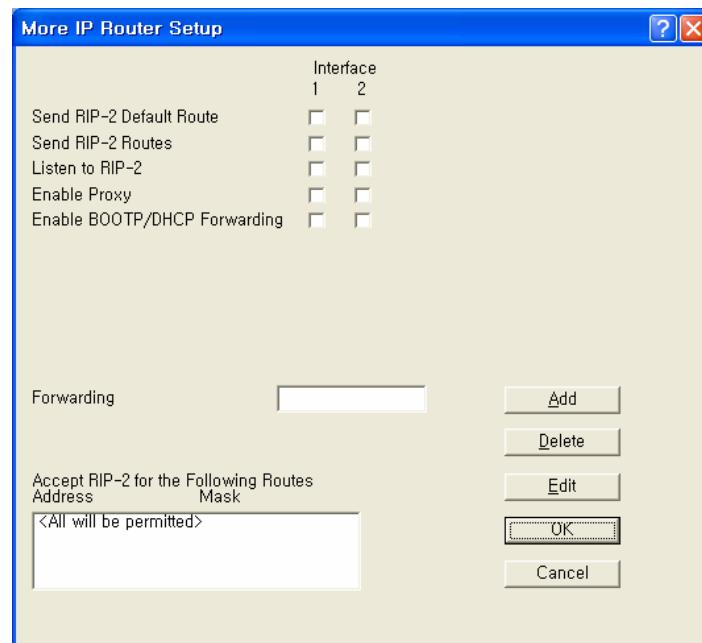

Send RIP-2 Default Route-- If the base station sends the Routing Information Protocol (RIP) default route (0.0.0.0) to other routers and hosts attached to a particular interface, select that interface's checkbox on the Send RIP Default Route line. By default, the base station will not send the Default Route on a particular interface unless this box is checked.

In the example shown in the screenshot, the base station will send RIP routes only on interfaces 1 and 2.

Send RIP-2 Routes -- If the base station should SEND Routing Information Protocol (RIP) Routes for routes of which it has knowledge to other routers on a particular interface, select that interface's checkbox on the Send RIP Routes line. By default, the base station will not send RIP Routes on a particular interface unless this box is checked. For the given example, the base station will send RIP Routes only on interface 1.

Listen to RIP-2-- If the base station should ACCEPT Routing Information Protocol (RIP) routes from other routers on a particular interface, select that interface's checkbox on the Listen to RIP line. By default, the Secure Data Mode Station will not accept RIP Routes from other routers, so you must select the interfaces if you wish to listen to RIP. For the given example, the Secure Data Mode Station will listen to RIP Routes on Interfaces 1 and 2, but will not accept RIP routes sent to it on interface 3.

Enable Proxy ARP-- Enabling Proxy ARP for a particular interface tells the base station that when it receives an ARP request for a particular client connected by that interface, that the base station itself should respond to the ARP Request, fulfilling the request with information that is in its IP ARP Table.

For example, Proxy ARP is enabled on interface 2. The IP ARP Table contains (among others) the following entry:

Table 4-7
IP ARP Table

Interface	Physical Address	IP Address	Media Type
2	00:60:1d:04:4d:88	10.7.3.5	dynamic

Since Proxy ARP is enabled for interface 2, when the base station receives a broadcast ARP Request for 10.7.3.5, instead of passing the ARP on to 10.7.3.5, the base station will answer the request with

information its own IP ARP table, that is: IP Address 10.7.3.5 -> MAC Address 00:60:1d:04:4d:88.

Proxy ARP is useful in many situations to reduce unnecessary network traffic, but is especially useful when you have clients in power-save mode, to prevent them from being 'woken up' whenever an ARP is done.

Enable BOOTP/DHCP Forwarding -- Select the interfaces for which you would like the base station to forward BOOTP and DHCP requests on to the BOOTP/DHCP server, which is specified in 'Forwarding Host'. Forwarding BOOTP and DHCP requests is necessary when the BOOTP/DHCP clients are not on the same IP subnet as the BOOTP/DHCP server.

If you are using BOOTP/DHCP, forwarding should most likely be DISABLED for the interface through which the BOOTP/DHCP server is located, and ENABLED for the other interfaces.

In the displayed screen, the BOOTP/DHCP Server is located via interface 1, so forwarding is enabled for interfaces 2 and 3, since clients on interfaces 2 and 3 have no other way of accessing the BOOTP/DHCP server.

Forwarding Host -- If you have enabled BOOTP/DHCP forwarding for one or more interfaces, enter the IP address of the BOOTP/DHCP server or relay agent to which you should forward BOOTP/DHCP requests.

In this example, the BOOTP/DHCP Forwarding host is 10.2.3.1.

Accept RIP-2 for the Following Routes-- In addition to the other Advanced IP Router features which allow you to accept RIP routes from particular interfaces, you can specify which RIP Routes you would like to accept. You are also able to specify the interfaces from which you would like to accept those particular RIP Routes.

The base station will accept RIP only for three particular routes. In the More IP Router Setup screen, it was specified that the base station should listen to RIP Routes on interfaces 1 and 2. This section further specifies that the base station should listen to the following RIP Routes ONLY:

- 10.17.42.0 (mask 255.255.255.0) only if it comes from interface 1
- 10.20.24.0 (mask 255.255.248.0) only if it comes from interface 2
- 10.220.23.0 (mask 255.255.255.0) on any interface

All other RIP routes will be ignored.

DHCP Server Setup

The DHCP Server Setup screen is used to set up the base station's Dynamic Host Configuration Protocol (DHCP) Server feature. The DHCP Server feature is a basic DHCP Server that can enable any and all wireless (or other) clients that connect to the base station to obtain their IP Address information from this Secure Data Mode.

Warning: If you have set up the base station to Obtain IP Address from DHCP Server on the IP Host Setup screen, do not enter anything in the Domain Name Info section of this screen. When the base station gets its own IP Address by DHCP, it will automatically determine the correct Domain Name information. You should, however, set up the IP Range and Gateway/Router Info section and select the correct interface.

Note: This screen is only available when the Enable DHCP Server checkbox has been selected on the General Setup screen.

Figure 4-59
DHCP Server Setup window
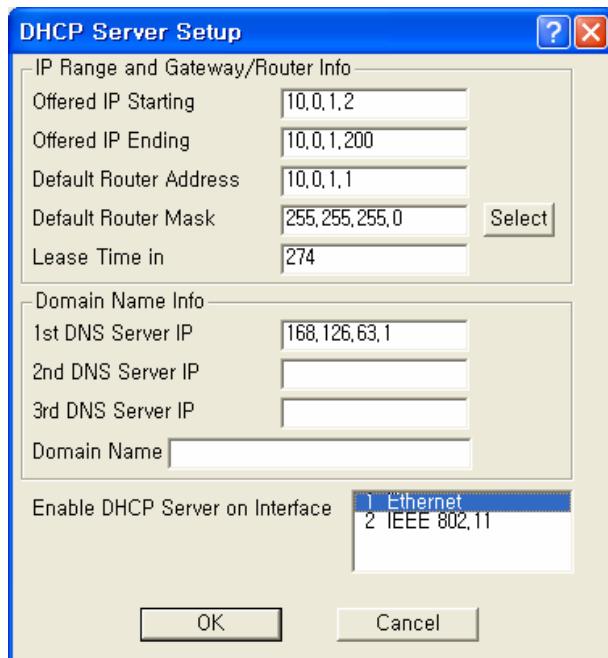

Offered IP Address-- Enter the beginning and ending IP addresses for the IP address range that the Secure Data Mode Station should offer to DHCP clients. When DHCP requests are received by the Secure Data Mode Station, it will offer the IP Starting Address to the first client, and increment the IP address offered to each consequent DHCP client until it reaches the IP Ending Address. IP Address leases must be renewed by

the DHCP client within the given Lease Time, or the IP Address will be made available to another client.

Note: The Secure Data Mode Station does NOT store DHCP address assignments between restarts. If the Secure Data Mode Station is rebooted, it will ARP for each address in the provided address range, recording which client is using which IP address.

Note: Be careful not to include the default router's IP address in the Offered IP
Address range.

Default Router Address-- Enter the default router IP address for the Secure Data Mode Station's DHCP clients.

Note: The default router IP address must be outside of the range defined by the Offered IP Starting Address and Offered IP Ending Address.

Default Router Mask-- Enter the subnet mask for the default router, or click the Select button to display the IP Mask List, and select a subnet mask from the list.

Lease Time in Minutes-- A DHCP lease is the amount of time that the DHCP server grants permission to the DHCP client to use a particular IP address. Enter the lease time (in minutes) for your DHCP server.

DNS Server IP Addresses-- Enter the IP address for the DNS server.

Warning: If you have set up the base station to Obtain IP Address from DHCP Server on the IP Host Setup screen, do not enter any DNS server IP addresses or a domain name. When the base station gets its own IP Address by DHCP, it will automatically determine the correct Domain Name information. You should, however, set up the IP Range (IP starting and ending addresses) and Gateway/Router Info section and select the correct interface.

Domain Name-- Enter the name of the domain.

Warning: If you have set up the base station to obtain IP Address from DHCP Server on the IP Host Setup screen, do not enter any DNS server IP addresses or a domain name. When the base station gets its own IP Address by DHCP, it will automatically determine the correct Domain Name information. You should, however, set up the IP Range (IP starting and ending addresses) and Gateway/Router Info section and select the correct interface.

Enable DHCP Server on Interface-- Select the interface on which you wish to enable the DHCP server.

Set Up Outgoing Network Address Translation (NAT)

Outgoing Network Address Translation (NAT) allows multiple computers to share a single IP address to connect to an IP network, including the Internet. This allows homes, small businesses, and Internet Service Providers to have Internet service for all of their computers without having to pay for additional IP addresses. The NAT feature serves as a simple firewall for incoming connections, since only traffic initiated by an interior computer is permitted through the NAT. In the screen shown below, when the client 10.0.1.1 wants to send data to the Internet, the access point will take the packet, replace the return address of 10.0.1.1 with 140.254.5.147, and then send the packet to the Internet. When a response comes from the Internet, the access point sends it to the correct client in the local address space.

Note: This screen is only available when the Enable Outgoing NAT checkbox has been selected on the General Setup screen.

Note: You do not need to turn on Outgoing NAT if you are using Incoming NAT, and vice versa. Incoming NAT only needs to be configured if servers in the local (private) address space need to connect with clients in the global (public) address space.

Figure 4-60
Outgoing NAT Setup window
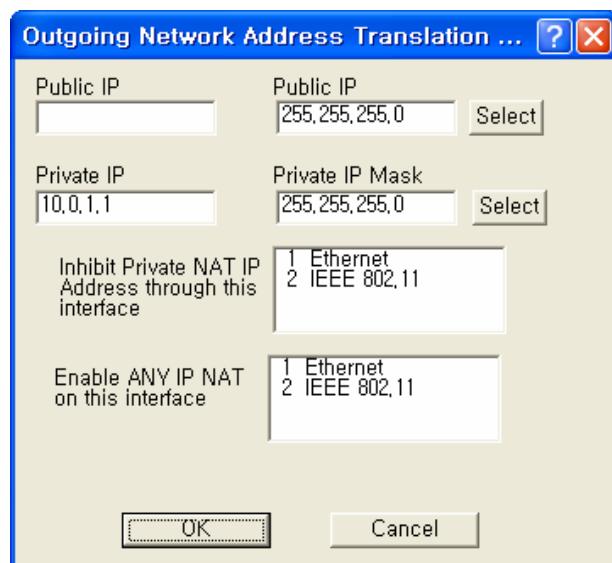

Public IP Address-- The IP address/mask seen by the external network.

Note: The IP address and subnet mask must be the same as the one in the IP Setup dialog under the Setup menu.

Public IP Mask-- The IP mask seen by the external network.

Note: The IP address and subnet mask must be the same as the one in the IP Setup dialog under the Setup menu.

Select IP Mask Button-- Clicking this button displays the IP Mask List, which the shows the IP Masks that can be used as public or private IP masks for outgoing NAT. The list consists of all possible subnet masks, and represents the range of addresses that will be translated.

Private IP Address-- The IP address that is seen by the local/internal network.

Note: The IP will be combined with the subnet mask, and the range of addresses that results will be translated. This range of IP set must match the addresses of the clients that connect to the base station.

Private IP Mask-- The IP mask that is seen by the local/internal network.

Note: The IP will be combined with the subnet mask, and the range of addresses that results will be translated. This range of IP set must match the addresses of the clients that connect to the base station.

Inhibit Private NAT IP Address through this interface

This option allows you to select one or more interfaces in which NAT will not be permitted. By default, no interfaces are selected. To select more than one interface, hold down the <Ctrl> key and click the names of the interfaces you wish to inhibit. Typically, you will inhibit the public interfaces because you will generally have users behind the private side (i.e., the private side is NATed to the public side).

Therefore, you must inhibit the interface used on the public side, whichever it may be. For example, in the screen shown below, the Ethernet 10.* network is NATed to the 140.* public wireless network. Therefore, NAT must be inhibited on the public interface, in this case the 802.11b interface. To do this, you would select 802.11b from the list, and click the OK button.

Set Up Incoming Network Address Translation (NAT)

Incoming Network Address Translations (NAT) is used to redirect requests to servers in the local address space based on the port of the request. If, for example, the client at local address 10.0.1.2 is serving web pages, and a request comes to the access point on that port for a web session, then the request will be forwarded to the web server on 10.0.1.2. The server will respond with the web page to the address of the original request.

Note: This screen is only available when the Enable Incoming NAT checkbox has been selected on the General Setup screen.

Note: Incoming NAT only needs to be configured if servers in the local (private) address space need to connect with clients in the global (public) address space. You do not need to turn on Incoming NAT if you are using Outgoing NAT, and vice versa.

To set up incoming NAT:

1. From the Setup tab, select General Setup. The General Setup screen is displayed.
2. Make sure that the Enable IP Routing checkbox is unchecked.
3. Select the Enable Incoming Network Address Translation checkbox, and then click OK to close the General Setup screen.
4. Click the Incoming NAT button on the Setup tab. The Incoming Network Address Translation Setup screen is displayed, and any public and private IP address/port pairs that you have previously defined are displayed in the window.

Figure 4-61
Incoming NAT Setup window
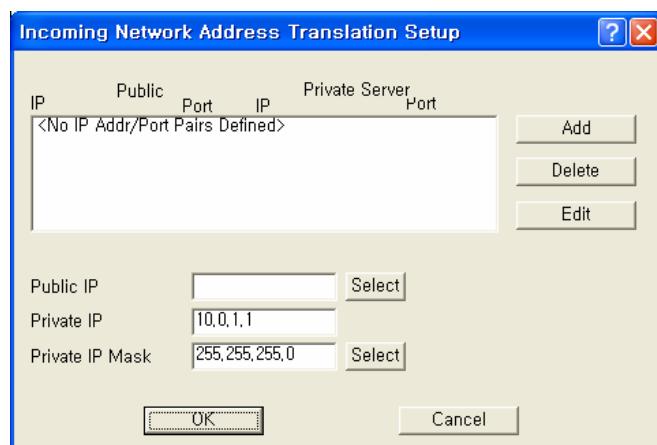

IP Addresses/Ports-- This window displays the public and private IP address/port pairs that you have previously defined.

Public IP Mask-- The public subnet mask for your local (internal) servers in the dialog. The public IP mask is paired with the Public IP address on the Input IP Address screen, as shown in the screens below.

Note: The public IP Mask must be the same subnet mask that was used in the setup of the external (or global) address of the base station.

Private IP Address-- The private IP address for your local (internal) servers in the dialog.

Note: The Private IP Address must be the same as the address and subnet mask that was selected for your internal network.
Private IP Mask-- The private subnet mask for your local (internal) servers in the dialog.

Note: The private IP Mask must be the same as the subnet mask that was selected for your internal network.

Add IP Address/Port Pairs-- Clicking the Add button displays the Add IP Address/Port Pair screen is used to add new pairs of incoming ports, and the IP address to which they should be directed.

Figure 4-62
Input IP address/Port (NAT) Setup window
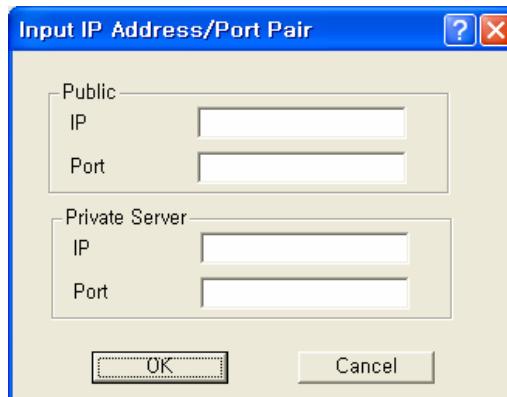

Public IP Address-- The public IP address for the service you wish to use. On the incoming NAT, there can only be one public address. You can map ports to specific local servers, but you must use the same public IP address, as configured on the incoming NAT screen.

Note: The Public IP address is paired with the Public IP mask on the Incoming Network Address Setup screen, as shown in the screenshots below.

Public Port-- The public port for the service you wish to use. For a discussion of the ports on which well known services run, see http://www.tatanka.com/doc/technote/tn0081.htm.

Note: The public IP address must be the same for different local servers, but the port will be different (e.g. different ports for SMTP, FTP, web servers, etc.).

Private Server IP Address-- The local (private) IP address of the server to which the request should be forwarded.

Private Server Port-- The local (private) port on the server to which the request should be forwarded.

Set up IP/UDP/TCP Filters-- Select the Firewall option from the Setup Tab to set up the IP TCP/UDP firewall (filtering) features.

IP Firewalls are used to restrict access between (sub) networks to certain IP hosts, types of IP packets, or connections to certain ports. You can set up the firewall to completely block all external IP traffic, or restrict access to certain machines, ports, or packet types.

Note: You must select the Enable IP/TCP/UDP Security Filters checkbox on the General Setup screen in order to access this screen.

Remote IP Address and Mask-- This column of the TCP/UDP Filter List displays the IP Address and Subnet Mask of the (un-trusted) remote sub network or machine for which you have chosen to set up this IP UDP/TCP filter.

Local IP Address and Mask-- This column of the TCP/UDP Filter List displays the IP Address and Subnet Mask of the local sub network or machine that is being protected by this particular firewall filter.

Figure 4-63
Firewall Setup window
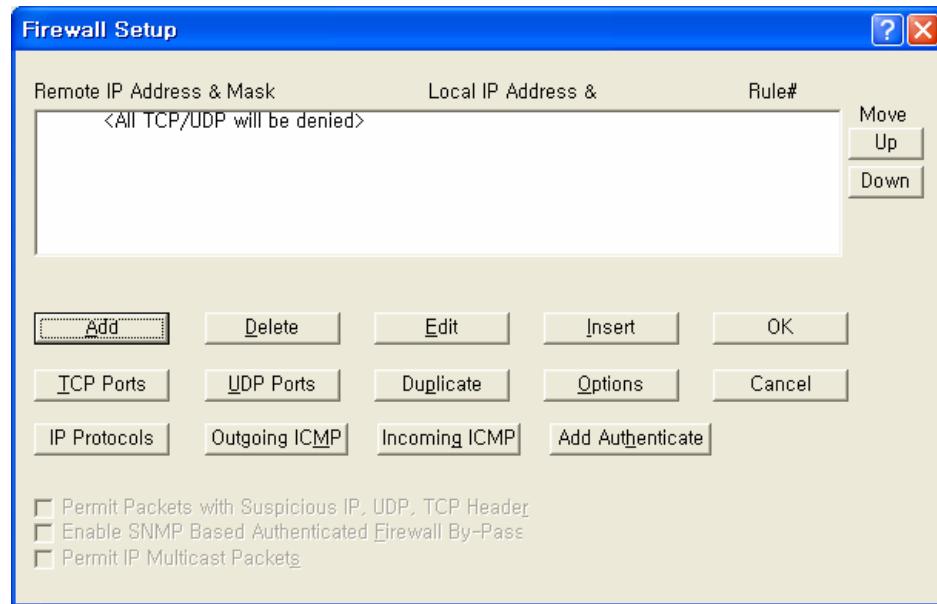

Add/Edit IP Address Mask Pair

The Add/Edit IP Address Mask Pair screen is used to enter both the IP
Address and Subnet Mask of both the local network (or machine) you
would like to protect and the remote network (or host) you would like to
protect it from.
A particular filter is applied only to traffic between the specific local and
remote networks (or hosts) shown in the list. If you wish to filter all
traffic, set the Remote IP Address and Subnet Mask both to '0.0.0.0'.

Figure 4-64
Input IP address (Firewall) Setup window

TCP Security Filters

To set the TCP ports to which a given filter will be applied, select the
filter you want to modify in the TCP/UDP Filter List and click the TCP
Ports button.

Figure 4-65
TCP Security Filter Setup window
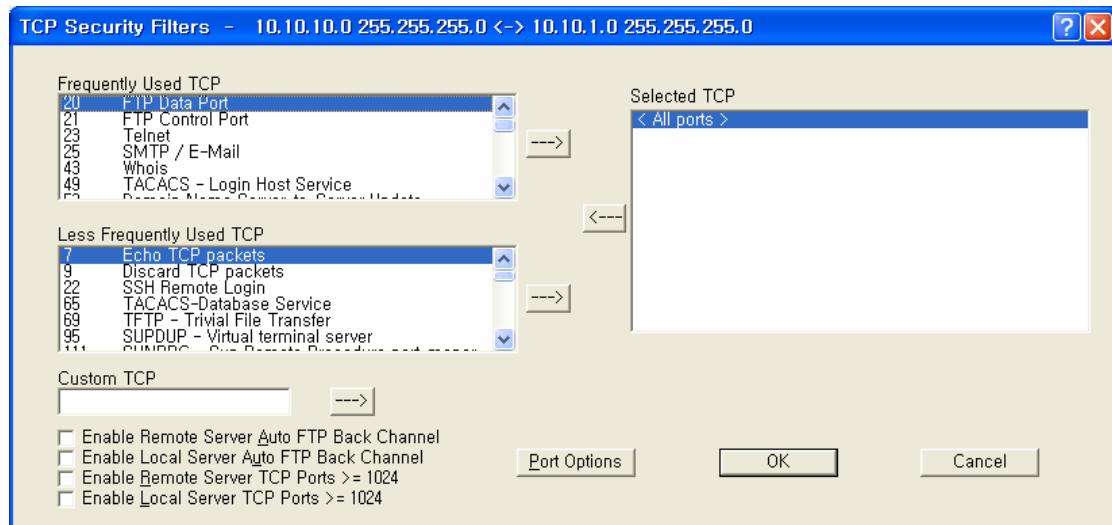

TCP Port Options

Clicking the Port Options button on the TCP Security Filter screen
displays the TCP Port Options screen. To set how the firewall filter is
applied for a given port, select the port (or the line labeled 'All other
ports') from the Selected TCP Ports list, and click on the 'Port Options'
button. This will display the window below, which you can click on for
more information. If you select the line 'All Other Ports' and then click
the 'Port Options' button, you will see a screen similar to the one
described in the UDP Port Options screen.

Figure 4-66
TCP Port Options Setup window
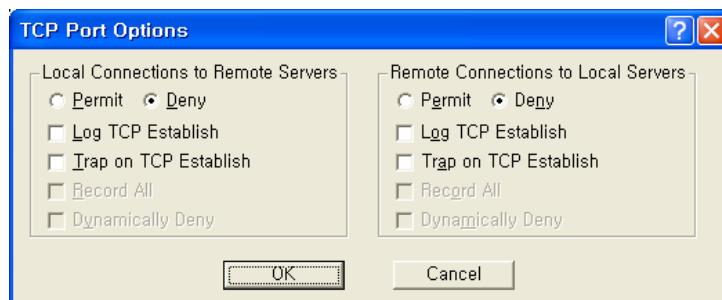

UDP Port Filters

To set the UDP ports to which a given filter will be applied, select the
filter you want to modify in the TCP/UDP Filter List and click the 'UDP
Ports' button.

Figure 4-67
UDP Port Options Setup window
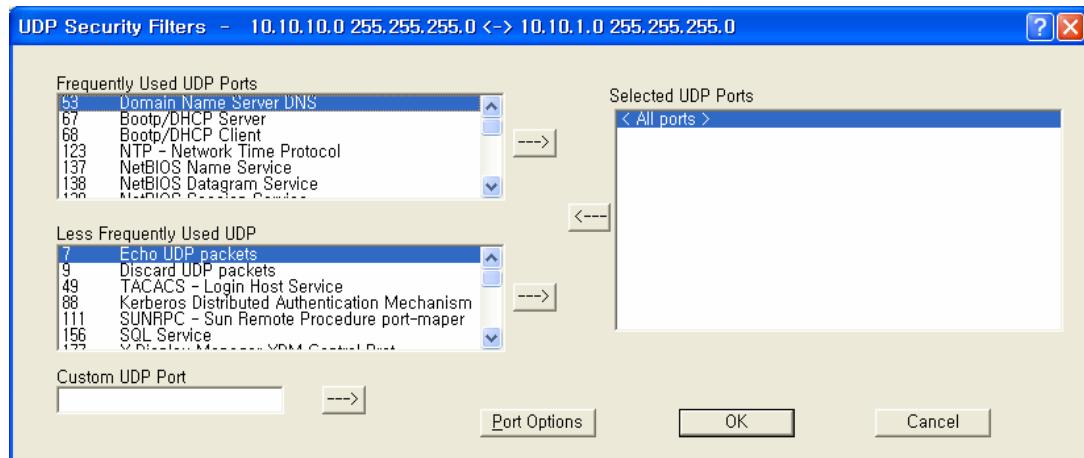

UDP Port Options

Clicking the Portion Options button on the UDP Security Filters screen displays the UDP Port Options screen. To set how the firewall filter is applied for a given port, select the port (or the line labeled 'All other ports') from the Selected UDP Ports list, and click on the 'Port Options' button. The window displayed below is for the 'All Other Ports' line, which sets the filter settings for all ports not explicitly listed in the Selected UDP Ports list. See TCP Port Options for an example using a specific port.

Figure 4-68
UDP Port Options Setup window
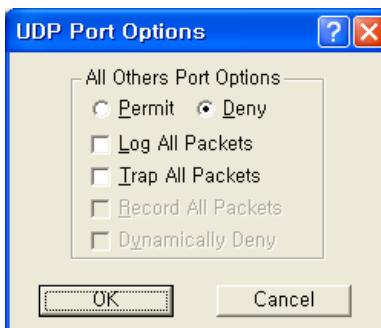

Firewall Setup Options

The Firewall Setup Options screen allows you to set handling options for a particular filter. Select the filter from the list on the Firewall Setup screen, and then click the Options button to display the following options. Alternately, you can simply double click the filter in the list to display the Firewall Setup Options screen.

Figure 4-69
Firewall Option Setup window
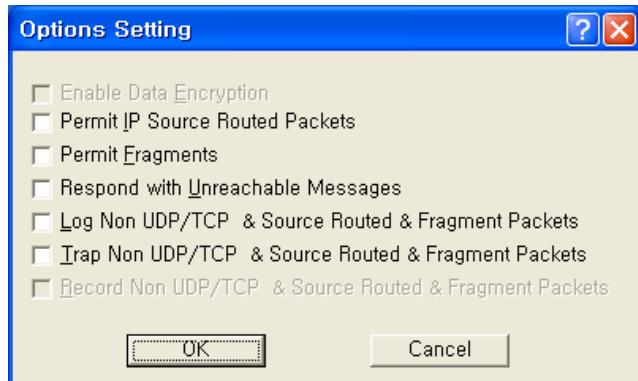

Enable Data Encryption-- Select this option if you wish to enable the data in packets sent between the IP hosts or subnets specified in this filter to be encrypted/decrypted by the Secure Data Mode Station. This option is not available if Data Encryption is not enabled on the General Setup screen.

Permit Non UDP/TCP Packets-- Select this option if you would like the Secure Data Mode Station to allow IP packets that are neither TCP nor UDP, such as ICMP. The firewall does not have specific filters for IP protocols other than TCP, UDP, and ICMP. If you want to deny other relatively rare protocols, do not select this checkbox.

Permit IP Source Routed Packets-- Select this option if you want the Secure Data Mode Station to allow Source-Routed IP packets to the local hosts protected by this filter. Source-Routed packets contain routing information inside the packet headers, instead of allowing network routers to decide the best route for the packet. They are primarily used in network troubleshooting, but may be used to 'fool' the firewall that the packets are coming from a trusted host. We strongly recommend that you do not permit source routed packets.

Permit Fragments-- Select this option if you would like the Secure Data Mode Station to permit fragmented IP packets to be passed through the firewall. IP packets may be incorrectly fragmented, creating security problems for hosts that may not properly handle incorrectly fragmented IP packets.

Respond with Unreachable Messages-- Select this option if you want the Secure Data Mode Station to respond to remote hosts attempting to connect to local machines with Destination Unreachable messages when the connection is denied by this security filter.

Log Non UDP/TCP & Source Routed & Fragment Packets-- Select this option if you want to log to the syslog for all packets that are not UDP/TCP, are source-routed, or are fragmented.

Trap Non UDP/TCP & Source Routed & Fragment Packets-- Select this option if you want the Secure Data Mode Station to SNMP Trap messages whenever a non-TCP or non-UDP, Source Routed, or Fragmented IP packet is received by the Secure Data Mode Station. SNMP Traps are sent to the SNMP Trap Host specified in SNMP Setup.

Record Non UDP/TCP & Source Routed & Fragment Packets-- Select this option if you want the Secure Data Mode Station to record all packets that are not UDP/TCP, are source-routed, or are fragmented.

IP Protocol Filters

Clicking the IP Protocols button displays the IP Protocol Filters screen, which allows you to set the IP protocols to which a given filter will be applied. Select the filter you want to modify on the Firewall Setup screen, and click the IP Protocols button.

Less Frequently Used IP Protocols-- This list displays some of the less commonly used protocols that run over IP If you wish to filter one of these protocols, select it and click the [->] button. Then set the action to take using the Protocol Options button.

Selected IP Protocols-- Select one of the protocols added to the list and then click the Protocol Options button to set the action for this protocol. Select "All Protocols" or "All Other Protocols" to set a default action when a packet is received from a protocol for which no action has been defined.

Figure 4-70
IP Protocol Filter Setup window

WLAN Cable Access Point 6220   NTPM99CA   Rel 1.0 Issue 1 Aug 2004
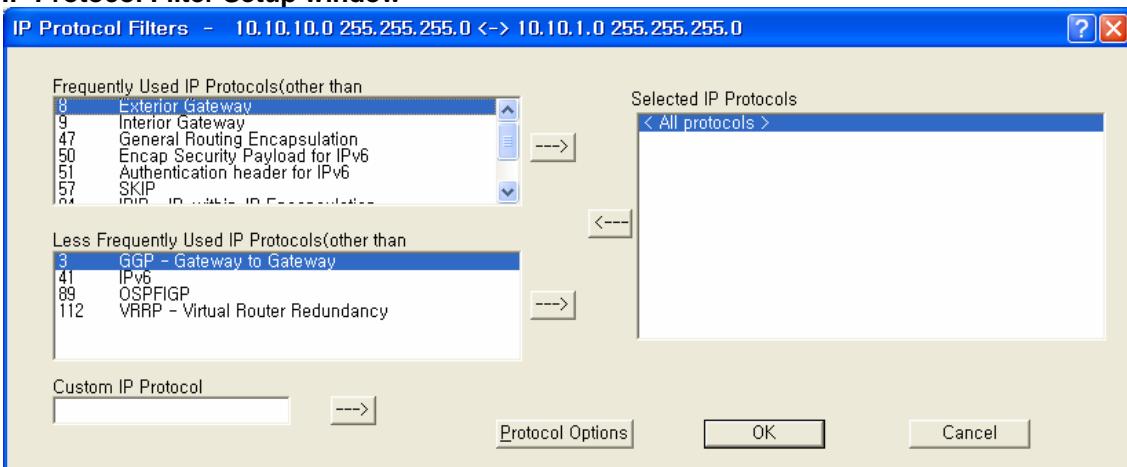

Custom IP Protocol-- If you wish to explicitly allow or deny access to a given IP protocol not listed in the two panels above, you can add that protocol to the list by simply typing it in the Custom IP Protocol field and clicking on the right arrow button [->] next to the text field. You do not need to add a protocol to the list unless you have specific requirements for that particular protocol.

IP Protocol Options

Clicking the Protocol Options button displays the IP Protocol Options screen, which allows you to define an action to take when data using that protocol is sent or received. When you select a protocol to filter, you will need to define an action to take when data using that protocol is sent or received. Initially, you will need to indicate whether you wish to permit or deny that protocol. In addition, you can optionally choose to log, trap, or record all packets, and to dynamically deny all other protocols.

Figure 4-71
IP Protocol Option Setup window
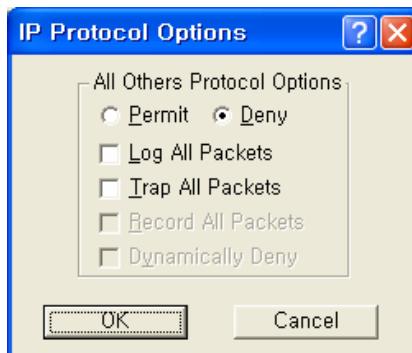

Permit All Other Protocols Button-- Select this button if you wish to permit all other protocols.

Deny All Other Protocols Button-- Select this button if you wish to deny all other protocols.

Log All Packets-- Select this checkbox if you wish to log all packets.

Trap All Packets-- Select this checkbox if you wish to trap all packets.

Record All Packets-- Select this checkbox if you wish to record all packets.

Dynamically Deny All Other Protocols-- Select this checkbox if you wish to dynamically deny all other protocols.

Outgoing ICMP Filters

Clicking on the Outgoing ICMP button on the Firewall Setup screen displays the Outgoing ICMP Filters screen, which allows you to permit or deny ICMP packets from going out from the local to remote interfaces. This allows you to deny diagnostic messages requested by internal (private) sources in this filter from being sent to external (un-trusted) machines.

Figure 4-72
Outgoing ICMP Filter Setup window
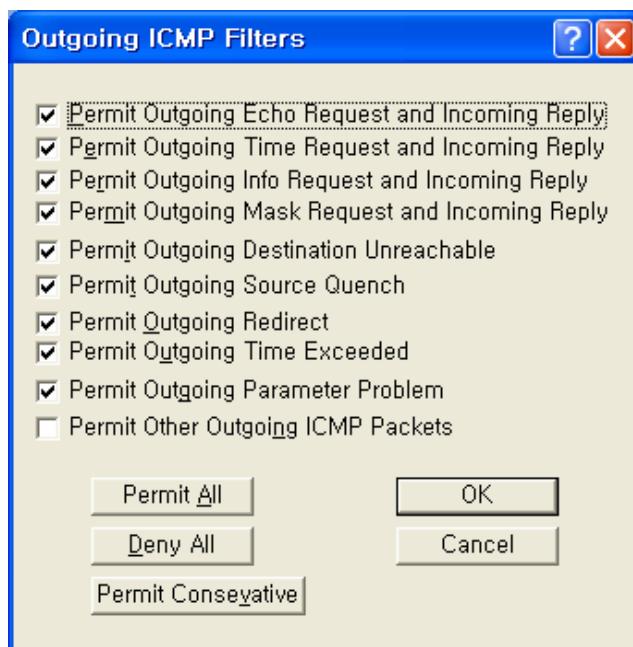

Permit Outgoing Echo Request and Incoming Reply-- Permit Echo (ping) Requests sent from local stations to remote stations, and the remote stations' replies.

Permit Outgoing Time Request and Incoming Reply-- Permit local stations' Time Requests sent to remote stations and the replies from remote machines.

Permit Outgoing Info Request and Incoming Reply-- Permit local stations' Information Request packets sent to remote stations, and the remote stations' replies.

Permit Outgoing Mask Request and Incoming Reply-- Permit local stations' Mask Request packets sent to remote stations, and the remote stations' replies.

Permit Outgoing Destination Unreachable-- Permit Destination Unreachable packets generated on the (private) local network to be sent to external machines
Permit Outgoing Source Quench-- Permit Source Quench messages generated by gateways on the local network to be sent to remote machines sending packets to that gateway.

Permit Outgoing Redirect-- Permit Redirect messages generated by gateways on the local network to be sent to remote machines sending packets to that gateway.

Permit Outgoing Time Exceeded-- Permit Time Exceeded messages generated by gateways on the local network to be sent to remote machines sending packets to that gateway.

Permit Outgoing Parameter Problem-- Permit the local network to send Parameter Problem messages to the remote network when there was a problem with the header parameters of a packet.

Permit Other Outgoing ICMP Packets-- Permit other ICMP packets not listed above to be sent from the local network to the remote network.

Permit All Button-- Clicking this button selects all checkboxes on the Outgoing ICMP Filters screen.

Deny All Button-- Clicking this button de-selects (un-checks) all checkboxes on the Outgoing ICMP Filters screen.

Permit Conservative Button-- Clicking this button automatically selects all checkboxes on the Outgoing ICMP Filters screen except for the Permit Other Outgoing ICMP Packets checkbox.

Incoming ICMP Filters

Clicking on the Incoming ICMP button on the Firewall Setup screen displays the Incoming ICMP Filter screen, which allows you to permit or deny ICMP packets from coming in from 'remote' to 'local' interfaces. This allows you to deny diagnostic messages requested from external (untrusted) sources in this filter from being sent to your local (private) machines.
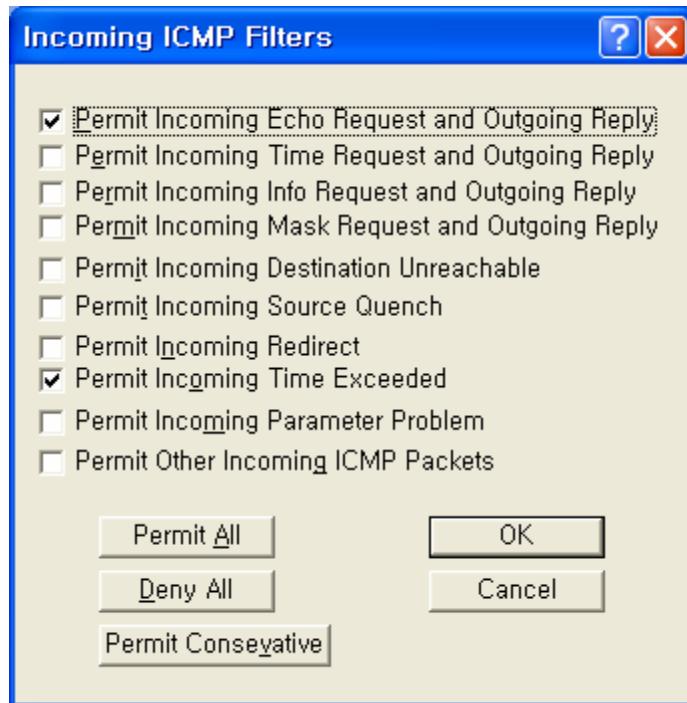

Permit Incoming Echo Request and Outgoing Reply-- Permit Echo
Requests sent from remote (un-trusted) computers to be sent to machines
on the local (private) network, and allow the local machine to reply to
them.
Permit Incoming Time Request and Outgoing Reply-- Permit Timestamp
Requests sent from remote (un-trusted) computers to be sent to machines
on the local (private) network, and allow the local machine to reply to
them.

Permit Incoming Info Request and Outgoing Reply-- Permit Information
Request packets sent from remote (un-trusted) computers to be sent to
machines on the local (private) network, and allow the local machine to
reply to them.

Permit Incoming Mask Request and Outgoing Reply-- Permit Mask
Request packets sent from remote (un-trusted) computers to be sent to
machines on the local (private) network, and allow the local machine to
reply to them.

Permit Incoming Destination Unreachable-- Permit Destination
Unreachable messages generated by remote computers to be sent to
machines on the local network.

Permit Incoming Source Quench-- Permit Source Quench packets generated by gateways on the remote network to be sent to gateways on the local network.

Permit Incoming Redirect-- Permit ICMP Redirect packets generated by gateways on the remote network to be sent to machines on the local network.

Permit Incoming Time Exceeded-- Permit Time Exceeded messages generated by machines on the remote network to be sent to machines on the local network.

Permit Incoming Parameter Problem-- Permit Parameter Problem messages generated by machines on the remote network to be sent to machines on the local network.

Permit Other Incoming ICMP Packets-- Permit other ICMP packets not listed above to be sent from the (un-trusted) remote network to the (private) local network.

Permit All Button-- Clicking this button automatically selects all checkboxes on the Incoming ICMP Filters screen.

Deny All Button-- Clicking this button automatically de-selects (un-checks) all checkboxes on the Incoming ICMP Filters screen.

Permit Conservative Button-- Clicking this button automatically selects the following checkboxes on the Incoming ICMP Filters screen:

- Permit Incoming Echo Request and Outgoing Reply
- Permit Incoming Destination Unreachable

All other checkboxes are automatically de-selected (unchecked).

Add Authentication Record

The Add Authentication Record screen is used to add an SNMP-based username/password firewall authentication bypass class. The Authentication class works much like a UNIX user group does; you can specify what types of packets a person in this authentication class can pass through the firewall when logged in with the approved username and password.

Figure 4-74
SNMP Authentication Record Setup window

Authentication Class Number-- Enter a number for an SNMP-based username/password firewall authentication bypass class. The Authentication class works much like a UNIX user group does; you can specify what types of packets a person in this authentication class can pass through the firewall when logged in with the approved username and password.

Administration

WLAN Cable Access Point 6220 (APU, CSU) have a various features about a management and operation listed below.

Save configuration

Saving the current configuration settings to the hardware device is a one-step process:

Use this File Menu option to save the base station configuration parameters to the location from which they were read. If the configuration was read from a base station, it will be saved to the APU and CSU from which it was read. If the configuration was read from a file, the modified configuration will be saved back to that file.
To import a saved configuration to an APU or CSU, first connect to the base station using Open Remote Config, then use Import Config File.

1. From the File Menu, select Save Config.

Figure 5-1
Save Config Menu
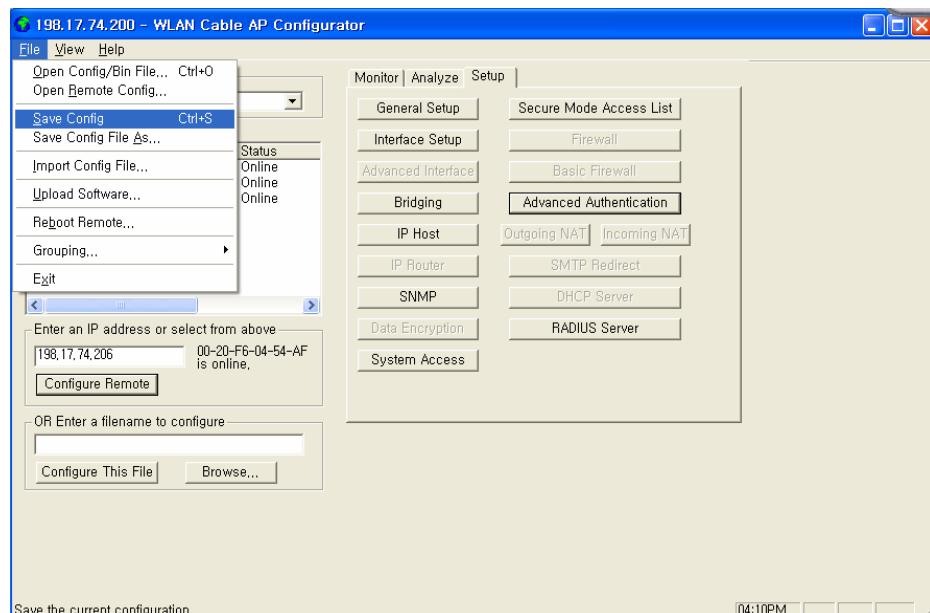

2. Click on the 'Yes' button

Figure 5-2
Confirm Save Config Window
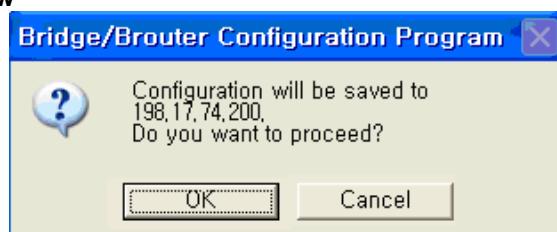

3. The message box will be displayed, as shown below, and then left click on the OK button.

Figure 5-3
Reboot Message Dialog Box

4. Just after this saving, APU or CSU will be restarting automatically.

Load new configuration

The 'import config file' option enables you to 'copy' the parameter values that you entered to configure the first Secure Data Mode Station to the other units. The "import config file" option enables you to 'copy' the parameter values that you entered to configure the first Secure Data Mode Station to the other units.

1. From the File menu, select Open/Config Bin File.

Figure 5-4
Open Config/Bin File Menu
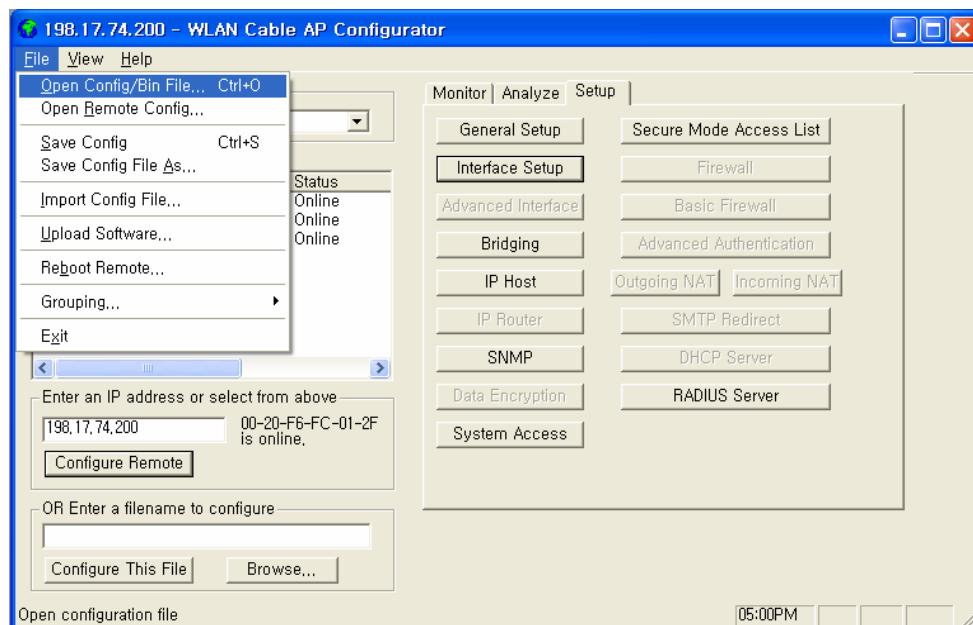

2. And the browse window will appear.

Figure 5-5
Open Config File Window
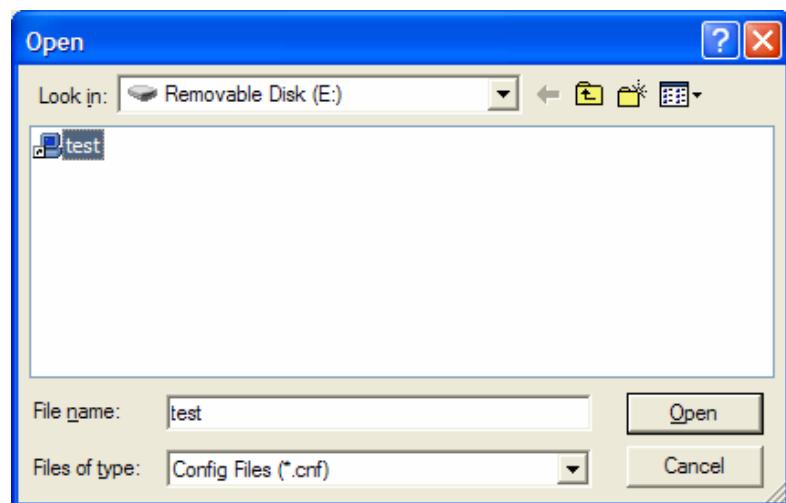

3. Select the configuration file in the specific folder, and Click 'Open' button,
4. Then, bridge/brouter Configuration Program" screen will appear.

Figure 5-6
Confirm Open Config File Dialog Box
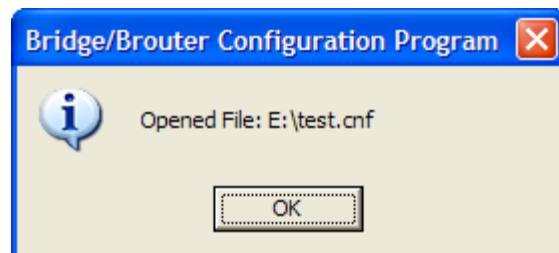

5. Left click on the OK button.

Load new license

There are ten steps that must be done to import the .bin file and its corresponding license file. Be sure you have downloaded and know the location of your files before you start.

1. From the File menu, select Upload Software, and the browse window will appear.

Figure 5-7
Upload Software Menu
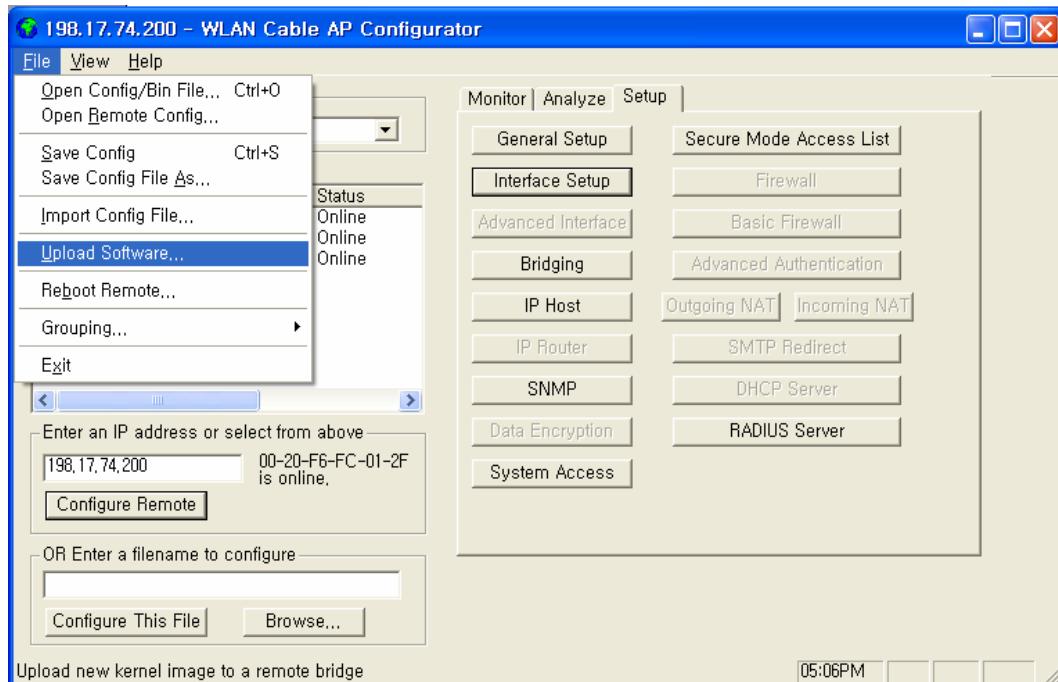

2. Browse to the location of your .bin file, and select it.

Figure 5-8
Open binary Window
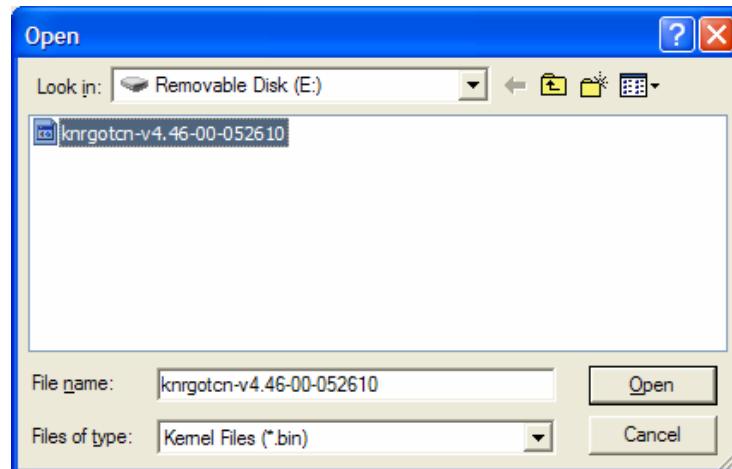

3. Click on the 'Open' button, and the "License Key Setup" screen will appear:

Figure 5-9
License Key Setup Window
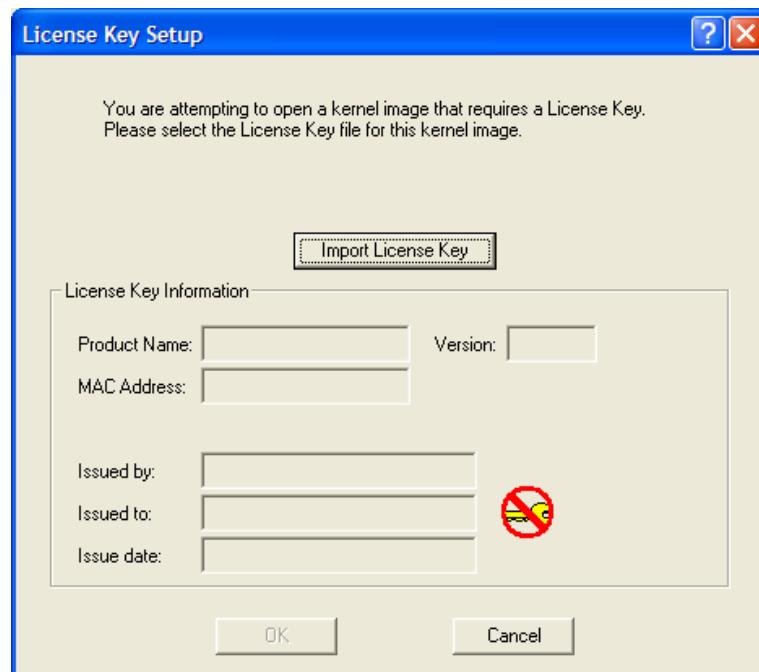

4. Click on the "Import License Key" button, and an "Open" dialog box will appear:

Figure 5-10
Open License Key Window

5. Select the license file that corresponds to the Ethernet MAC of the unit you are working with. (If you have "Licenses for this MAC address" selected in the file type drop box, only the licenses for the MAC of the current unit will appear.)
6. Click on the 'Open' button

Figure 5-11
License key setup window
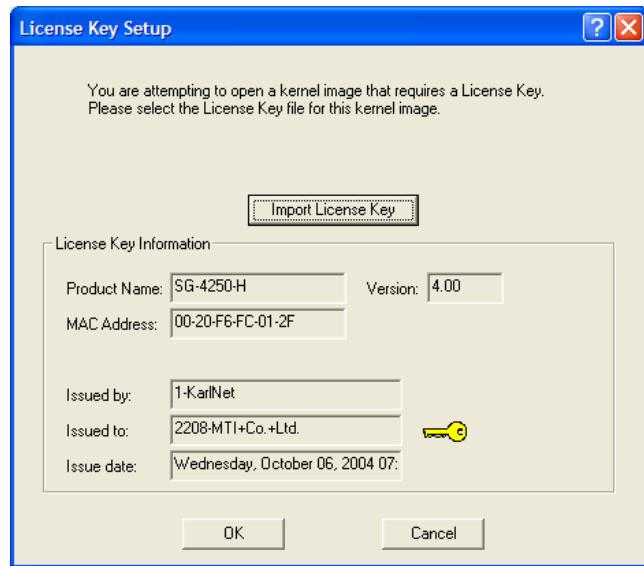

7. Click on the 'OK' button

Figure 5-12
Setup window
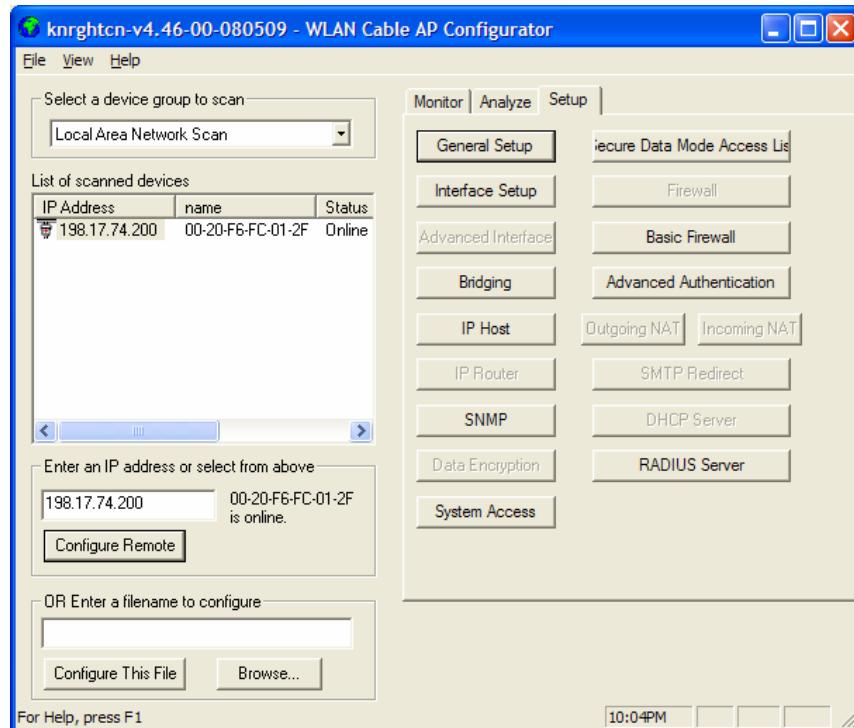

8. You can see an initial setup windows and then, From the File menu, select upload software as below.

Figure 5-13
Selecting Upload Software
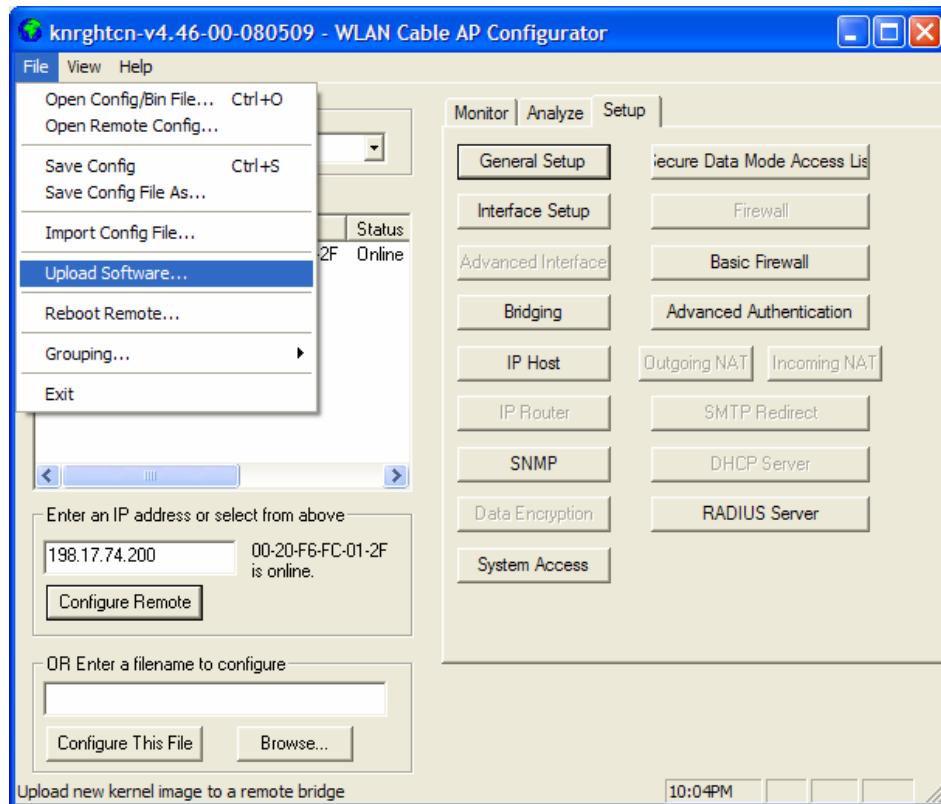

Figure 5-14
Enter IP address dialog

9. Enter the IP address of the unit to upload new software binary and Click on the 'OK' button.

Figure 5-15
Uploading Confirmation Dialog 1

Troubleshooting

1. **APU Power cannot be Turned ON.**

    Check if a CATV Power (45VAC ~ 95VAC) is supplied thorough coaxial line by measuring an AC Voltage Level.
    If no power signal is detected at the end of coaxial cable, you should search a problem point on CATV Network while moving up toward ONU and UPS Power supply.

2. **LED 2(Link 1) is continuously blinking after running a long time and all network entity including APU cannot receive IP address from DHCP server.**

    Measure RF signal level at the end of coaxial cable or monitoring port in APU enclosure. And check if RF signal level is beside the range of signal required or not. If so, you should adjust the power level by tuning all related network facility to meet the requirement for operation of Cable Modem.
    * Normal Power level (DOCSIS) : +15 to -15 dBmV

3. **LED 3(Link 2)/LED 4(Radio Link) are turned off.**

    In the AP Configurator, select and click the setup tap, move to "interface" and See if Ethernet 2 and 802.11 is enabled or not. If disabled, check each interface.
    If the LED lights are still turned off in spite of this work, APU system may be failed so that you should contact Nortel local representative or technical support center.

4. **How do I see and configure a setup parameter of CSU without radio connection to APU?**

    The only devices that will display in the Configurator local scan window are the units in the same subnet as your management computer. The device in question would not display in your local scan window.
    Therefore, you should change IP address (Client PC) to any one of the subnet IP address group "198.17.74.XXX". and then, you can find out CSU entity having IP address "198.17.74.254".

5. **Why can CSU setup a radio connection to APU?**

    Such a situation is caused by a various reason as below:
    -   Mismatching between the radio setup parameter of APU and that of CSU
        + Radio Channel
        + Network ID (NWID)
        + WEP Encryption Key
    -   Radio Link Designing Problem(Link Distance, Antenna Direction and so on)

6. **How many CSU subscribers can connect to a single WLAN Cable Access Point (APU Secure Data mode)?**

   Currently, the highest number of CSU Secure Data mode connections per APU Secure Data mode Base Station mode is 8 due to the restriction of allowed user a t the cable modem. Conventionally, DOCSIS Cable Modem supports only 15(Fi fteen) users or entries, which means only at most seven(7) PC clients can connec t to public network except eight(8) CSU.

7. **How does the number of CSU Secure Data modes affect wireless throughput?**

   As more CSU Secure Data modes are added, the APU Secure Data mode Base S tation mode is still able to effectively manage the throughput of the overall wirel ess link. Just as on any shared medium, each station's throughput is determined b y the overall usage of the wireless link. The more stations transmitting on the lin k at a time, the lower each individual station's throughput goes. However, Secure Data mode performs in such a way that up to a point, the more heavily loaded th e network becomes, the higher the overall throughput becomes.
   For example, due to the intricacies of our Adaptive Dynamic Polling algorithms and Secure Data mode 'fairness' principles, a single-user FTP session does not use all of the possible wireless bandwidth. But when performing several different transfers to and from different CSU Secure Data modes, the actual overall bandwidth of the Secure Data mode network increases. In general, the heavier a Secure Data mode network is loaded, the higher the total bandwidth used becomes.

8. **How do I check throughput?**

   Network throughput can be tested and analyzed using the Ping Fill test. This test dynamically fills the network connection with ICMP Echo (ping) packets and w aits for the responses from the target station. Since each packet sent is echoed ba ck to the sender, this tests the overall wireless throughput in both directions.
   Choosing the correct parameters is crucial to obtaining accurate Ping Fill test res ults. The speed at which the target station responds to the ICMP Echo packets is crucial to correctly assess the speed of the wireless link.
   The IP stacks in some PC operating systems, such as Microsoft Windows, often do not respond quickly enough to the ICMP Echo packets to obtain an accurate a ssessment of your network throughput. When running the Ping Fill test to a Micr osoft Windows system, your results may be slightly lower than normal throughp ut.

9. **How do I read the configuration from a device if I cannot see the unit in the local scan window?**

   The only devices that will display in the Configurator local scan window are the

units in the same subnet as your management computer. For example your PC ha s an IP address 64.22.33.13 with a subnet mask of 255.255.255.0 and your devic e has an IP address of 65.23.11.2 with a subnet mask of 255.255.0.0. The device in question would not display in your local scan window.

 Even though you may be able to ping the unit it may not be visible in the local s can window. In the Configurator, select the file menu, and then open remote con fig and then type in the IP and the password. It may be necessary to select the "t his device is in my local subnet" check box to actually read the configuration fro m the unit. Attempt to read the configuration with it un-checked first. If the confi guration cannot be read try with this box checked.

10. **I seem to have lost or forgotten the read/write password to manage my product.**
How can I get back in to manage the unit?

If the read/write password has been lost or forgotten there is only one thing that can be done about this in order to be able to manage the unit again. The unit mus t be put into force reload mode and the firmware must be reloaded. All configura tion settings will be lost. Physical access to the unit is required in order to accom plish this procedure.

11. **I am performing a wireless link test from a CSU Secure Data mode and one of my C SU Secure Data modes on the other side of my base station is showing up, is this a problem?**

It is a normal function to be able to see the other units in the wireless link test thi s way. This shows you what devices are within range that the radio can "hear". As long as the units are set as Secure Data mode CSU Secure Data modes, there are no way they will actually be communicating with each other. They are receiv ing radio signals from each other that they have to interpret and dump. This is no t an optimal solution and should be changed when it is practical to do so by isola ting antennas, changing polarity or reducing output power if possible.

12. **Please provide the list of parameters for the different levels of signal strengths i.e. No Connection, Poor, Acceptable, Good, and Excellent. How do I determine what is good and bad?**

What these values will mean, is somewhat specific to the environment being worked under. For example, a Signal to Noise Ratio of 15 may be fine for one area and 15 may not work very well in a high noise area. So here are some gener al guidelines, Keep in mind all the information below is related to Secure Data mode, for 802.11b mode replaces retransmit with dropped packets:

There are some further items to note:
Link planning should be done in your general geographic area and your links sh ould be set up with an extra margin that your company determines.

Links are best performed when possible with high gain antennas as opposed to l ow gain amplified antennas

Noise is typically introduced by failing amplifiers and problems with connectors and defective radios. Signal typically drops with bad cabling, connectors or ante nna misalignment, radio power issues Network ID and Channel values being the same, may help stability in marginal links

Marginal (sporadic links) typically occur in SNR ranges from 5-9, 10-15 usually will keep association with retransmits or some packet loss.SNR from 16 and up usually are acceptable for every day operation.

If SNR is over 25 and throughput is poor it overdriving or multi-path may be the cause of the problems.
Secure Data Mode Station Entries - Provides information on octal packet, retrans mitted packets and failed packets. A value other than 0 under failed packets typi cally points to a link issue. Keep in mind TC retransmits a packet 9 times, (with the initial packet 10 total).

This has occurred and the packet has been dropped when a failure occurs. Retran smits should be 15% or less of total transmits, this may indicate signal, noise or antenna alignment issues.

Remote Statistics - Check each Ethernet Interface, any errors or collisions may b e signs of link speed or greater network related issues.

Check each wireless interface. Specifically, compare the Frame Check Sequence errors to the bytes in values. Typically FCS occurs on any wireless connection. This should only be a concern if the value exceeds approximately 10% of the by tes in value. This may be an indicator of signal/multi-path issues.

13. Can I block unwanted MAC addresses from the Ethernet interface?

It is possible to set an Access Control List to set all of your allowable MAC's on the Ethernet (everything else on the Ethernet will be denied) by reading the confi guration from the unit with the WLAN Cable AP Configurator. Go to the Setup t ab -- General Setup -- Select the Mac Authentication Access control radio button and click OK. Then select the Setup tab -- Advanced Authentication -- check th e Access Control List and then click the Setup button. Add all your allowable M AC's and select the Ethernet interface to apply the ACL.

Appendix A. Specification

Access Point Unit(APU)

General

- o Case: Aluminum alloy steel (Waterproof, EMI protection, Vibration Robust)
- o Size: 300 (W) x 232.6 (L) x 112 (D) (mm)
        11.81 (W) x 9.157 (L) x 4.40 (D) (inch)
- o Weight(without antenna): 3.14 Kg / 6.9234 lbs
- o Elements: Access Point, Cable Modem, HFC Signal Filter, Power Supply Unit
- o Ports: Coaxial Cable Port, Monitoring Port, Antenna Port (N-type)
- o LED Panel: Power, Cable Modem Link, LAN, WLAN, CM-AP Link
- o Temperature: -40 ~ 65 ℃ (Operating)
- o Power supply: Input Power 45 ~ 95VAC (Supplied by CATV UPS)
              Output Power 3.3VDC (3A), 9VDC (1.5A)
- o Power Consumption : MAX 12W (Current < 0.5A)

Hardware

Radio Card
- o Operation Frequency: 2.4 ~ 2.4835GHz (ISM Band; a/b/g ready with radio upgrade)
- o Wireless LAN standard: IEEE 802.11b (a/b/g ready w/ radio upgrade)
- o Frequency: 2.4GHz ISM band(North America 11 Channels)
- o Modulation: Direct Sequence Spread Spectrum (DBPSK, DQPSK, CCK)
- o Data rate: 1M, 2M, 5.5M, 11Mbps with auto fall-back
- o Receive sensitivity: Min. -83dBm at 11Mbps

HFC Filter
- o Input Signal : HFC Signal(-15dBmV ~ +15dBmV), AC Power (45VAC ~ 95VAC/ Max: 135VAC)
- o Output : AC Power, HFC Signal, Monitoring Signal(Attenuated by 20dB)

Power Converter (AC-DC)
- o Input Voltage Range: 45 VAC ~ 135VAC
- o Output Voltage/Current: +3.3Vdc(3A), +9V(1.5A)

Software

- o Firmware : APU Secure Data Mode(Base Station), Wi-Fi Access Point
- o Wireless Service Protocol : Secure Data Mode, Dynamic Polling
- o 802.1x - MD5, TLS, TTLS, PEAP over EAP
- o MAC access control – 32 local MAC Address Table
- o Standard RADIUS server support
- o Wired Equivalent Privacy encryption - 64, 128
- o Firewall(ICMP/UDP/TCP/IP Protocol Filtering)
- o Layer 2 Protocol Filtering
- o BOOTP/DHCP(Server, Relay, Client), Static IP
- o NAT(Incoming/Outgoing)
- o Routing Protocol(RIP v2, Static)
- o Restriction of Broadcast Storm
- o SNMP v1, Software upgrade via TFTP
- o GUI Program : Windows Based
- o Throughput Analysis: Ping Fill
- o Radio Performance Testing Tool: Antenna Alignment
- o Remote Statistics Monitoring
- o SNMP Traps
- o MIB II

Cable Modem Specification (Hardware / Software)

- o Standard : DOCSIS 2.0 compliant
- o Frequency : 5~42MHz (Upstream), 88~860MHz (Downstream)
- o Modulation : QPSK/16QAM/64QAM/128QAM(Upstream),
                 64QAM/256QAM (Downstream)
- o Data Rate: 5.12Mbps/QPSK, 30.34Mbps / 64QAM (Upstream)
                 30.34Mbps/64QAM, 42.88Mbps / 256QAM (Downstream)
- o Channel Bandwidth
  Upstream: 200 KHz, 400 KHz, and 800 KHz, 1.6 MHz, 3.2 MHz, 6.4 MHz
  Downstream: 6MHz
- o Error correction : Reed-Solomon (Upstream), Reed-Solomon
  Trellis(Downstream)
- o Signal Level : + 8dBmV ~ + 53dBmV(All Modulation),
                 -15dBmV ~ + 15dBmV
- o Input Impedance: 75 Ohm
- o Interface: RJ 45 Ethernet port, USB 1.1 port
- o SNMP v1, Software upgrade via TFTP

Corporate service unit (CSU)

General

- o Case: Aluminum alloy steel (Body), RADOME
- o Size: 180 (W) x 239 (L) x 81 (D) (mm)
          7.08 (W) x 9.40 (L) x 3.19 (D) (inch)
- o Weight: 1.3 Kg / 2.8659 lbs
- o Elements: Access Point, POE Splitter, Built-in Antenna in CSU body, RADOME
- o Ports: POE Ethernet Port(RJ-45/CAT5), 12V DC Jack
- o Temperature: -40 ~ 65 ºC (Operating)
- o Power supply(Option): 802.3af compliant POE Injector(45V DC, 315 mA)
- o Power Consumption : MAX 10W (Current < 0.4A)

Hardware

Radio Card
- o Operation Frequency: 2.4 ~ 2.4835GHz (ISM Band; a/b/g ready with radio upgrade)
- o Wireless LAN standard: IEEE 802.11b (a/b/g ready w/ radio upgrade)
- o Frequency: 2.4GHz ISM band(North America 11 Channels)
- o Modulation: Direct Sequence Spread Spectrum (DBPSK, DQPSK, CCK)
- o Data rate: 1M, 2M, 5.5M, 11Mbps with auto fall-back
- o Receive sensitivity: Min. -83dBm at 11Mbps

POE Splitter
- o IEEE 802.3af Compatible
- o Input Signal : DC Power (48V DC, Max 315mA), Base-band Signal(Ethernet)
- o Output : DC Power(3.3V DC), Base-band Signal(Ethernet)

POE Injector
- o IEEE 802.3af Compatible
- o Input Signal : AC Power (90~264V), Base-band Signal(Ethernet)
- o Output : POE Signal(DC Power(48V), Base-band Signal(Ethernet))

Software
- o Firmware : CSU Secure Data Mode(Subscriber Station), Wi-Fi Access Point
- o Wireless Service Protocol : Secure Data Mode, Dynamic Polling
- o 802.1x - MD5, TLS, TTLS, PEAP over EAP
- o MAC access control – 32 local MAC Address Table
- o Standard RADIUS server support
- o Wired Equivalent Privacy encryption - 64, 128

o Firewall(ICMP/UDP/TCP/IP Protocol Filtering)
o Layer 2 Protocol Filtering
o BOOTP/DHCP(Server, Relay, Client), Static IP
o NAT(Incoming/Outgoing)
o Routing Protocol(RIP v2, Static)
o Restriction of Broadcast Storm
o SNMP v1, Software upgrade via TFTP
o GUI Program : Windows Based
o Throughput Analysis: Ping Fill
o Radio Performance Testing Tool: Antenna Alignment
o Remote Statistics Monitoring
o SNMP Traps
o MIB II

Appendix C. Antenna Type

NTA.2407 Panel Antenna

The NTA-2407 is a compact, light-weight, vertically polarized panel antenna intended to mount to the APU Enclosure. The antenna consists of a printed patch array enclosed in an aluminum cavity with a UV stabilized ASA radome. The antenna is sealed and intended for outdoor use.

Mechanical Specifications

Length: 8 in. (203 mm)
Diameter: N/A
Width: 11 in. (279.4 mm)
Depth: 0.44 in. (11 mm)

Weight (incl. hardware): 1.66 lb. (0.75 kg)
Rated Wind Velocity: 125 mph (200 km/h)
Horizontal Thrust at rated wind: 38 lb. (17.2 kg)

Mechanical Tilt: 0 +/- 22.5° Pan
Mounting: Mounts to APU Enclosure

Pig-Tail Length: N/A

Electrical Specifications

Frequency Range: 2400-2483 MHz
Gain: 14 +/- 1 dBi
VSWR: 2.0:1 max.
Polarization: Vertical
Power: 20 Watts
H-Plane Beamwidth: 27 degrees
E-Plane Beamwidth: 36 degrees
Front to Back Ratio: 25 dB min. (azimuth)
Cross Pol. Descrimination: 13 dB min.
Electrical Beamtilt: N/A
Impedance: 50 ohms nominal
Termination: SMA female

Material Specifications

Radiating Elements: Plated copper on PCB
Reflector: Irridited aluminum
Radome: Gray UV stabilized ASA
Mounting Hardware: Aluminum and HDG steel

Radiation Patterns/Masks
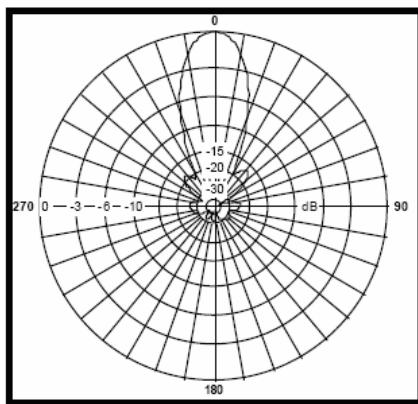

H-Plane

E-Plane
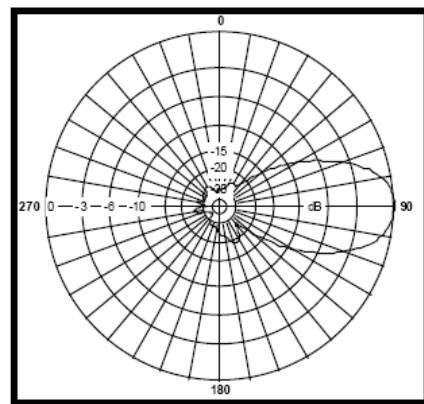

NTA.2412 Bidirectional Antenna

The NTA-2412 is a vertically polarized birdirectional antenna intended to mount to the APU Enclosure. The antenna consists of a printed dipole array enclosed in a UV stabilized ASA radome for superior weatherability. It is designed for wireless data in the ISM band and is at DC ground to aid in lightning protection.

Mechanical Specifications

Length: 10.5 in. (267 mm)
Diameter: 3 in. (76 mm)
Width: N/A
Depth: N/A

Weight (incl. hardware): 2 lb. (0.9 kg)
Rated Wind Velocity: 125 mph (200 km/h)
Horizontal Thrust at rated wind: 9 lb. (4 kg)

Mechanical Tilt: N/A
Mounting: Mounts to APU Enclosure

Pig-Tail Length: 12 in. (304.8mm)

Electrical Specifications

Frequency Range: 2400-2483 MHz
Gain: 9 dBi (peak)
VSWR: 1.5:1 max.
Polarization: Vertical
Power: 5 Watts
H-Plane Beamwidth: 60 degrees
E-Plane Beamwidth: 28 degrees
Front to Back Ratio: N/A
Cross Pol. Descrimination: 20 dB min.
Electrical Beamtilt: N/A
Impedance: 50 ohms nominal
Termination: N male

Material Specifications

Radiating Elements: Plated copper on PCB
Reflector: Irridited aluminum
Radome: Gray UV stabilized ASA
Mounting Hardware: Aluminum and HDG steel

E-Plane
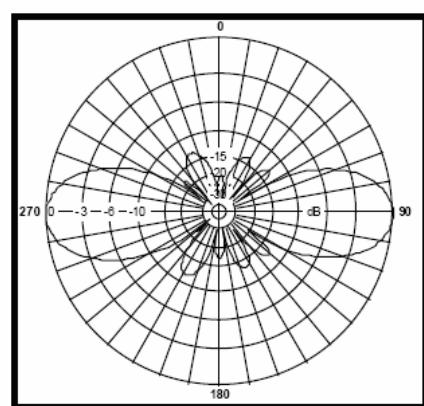

NTA.2400 Omni directional Antenna

The NTA-2400 is a vertically polarized, medium gain, omni-directional antenna that covers the 2.4-2.5 GHz ISM band. This antenna is a robust point to multi-point antenna designed to be completely waterproof. The antenna is intended to mount to the APU Enclosure.

Mechanical Specifications

Length: 26 in. (660 mm)
Diameter: 3.9 in. (100 mm)
Width: N/A
Depth: N/A

Weight (incl. hardware): 1.25 lb. (0.57 kg)
Rated Wind Velocity: 125 mph (200 km)
Horizontal Thrust at rated wind: 7 lb. (3.2 kg)

Mechanical Tilt: N/A
Mounting: Mounts to APU Enclosure

Pig-Tail Length: N/A

Electrical Specifications

Frequency Range: 2400-2483 MHz
Gain: 7 dBi typ.
VSWR: 2.0:1 typ.
Polarization: Vertical
Power: 5 Watts
H-Plane Beamwidth: 360 degrees
E-Plane Beamwidth: 14 degrees typ.
Front to Back Ratio: N/A
Cross Pol. Descrimination: 18 dB typ.
Electrical Beamtilt: N/A
Impedance: 50 ohms nominal
Termination: N female

Material Specifications

Radiating Elements: Copper
Reflector: N/A
Radome: Gray UV stabilized PVC
Mounting Hardware: Aluminum and Stainless steel

ET-PR12 Built-in Panel Antenna

The ET-PR12 is a compact, light-weight, vertically polarized panel antenna intended to built in the CSU Enclosure. The antenna consists of a printed patch array enclosed in an aluminum cavity with a UV stabilized ASA radome. The antenna is sealed and intended for outdoor use.

Electrical Specifications

Frequency Range : 2400~2500 MHz

Gain : 12.0dBi (Minimum)

VSWR : 1 :1.5 (Typical)

Polarization : Linear (Vertical or Horizontal)

Power : 3 Watts

H-Plane Beam width : 35 degrees

E-Plane Beam width : 35 degrees

Front to Back Ratio : > 30dB

Cross Pol. Discrimination : 20 dB min.

Electrical Beam tilt : N/A

Impedance : 50 ohms nominal

Termination : SMB male

Mechanical Specifications

Length : 7 in. (180mm)

Diameter : N/A

Width : 7 in. (180mm)

Depth : 0.79 in. (20mm)

Weight (Incl. hardware) : 1.0kg

Rated Wind Velocity : 75 N (160 km/h)

Horizontal Trust at rated wind : 75 N (160km/h)

Mechanical Tilt : 90° ~ - 45°

Built-in : Built in CSU Enclosure

Pig-Tail Length : N/A

## Material Specifications

Appendix E. Site Survey

Calculating the system parameters

Free Space

Microwave signal will be attenuated as it travels through space according to the following equation

$Gs = Ptx + Gtx + Grx - (RS)$

Gs : System Gain
Ptx : Transmit power level in dBm
Gtx : Transmit antenna gain in dBi
FSL: Free space loss attenuation in dB
Grx : Receive antenna gain in dBi
RS : Receiver Sensitivity in dBm

$Lt = FSL + Mp$

Lt : Transmission Loss
FSL : Free Space Loss
FM : Fade Margin + Other Loss(Cable)

$FSL : 92.4 + 20Log(F) + 20Log(R)$

F: Frequency (MHz)
R: Range (Km)

Radio Signal transmitted at one side can be reach the other end only when the system gain is equal or larger than Transmission Loss.
An install engineer should determine the antenna gain at both sites to meet the above condition while EIRP, the summation of the antenna gain and the output power do not exceed Radio Regulation (FCC)

Figure A.5
Radio Link Analysis
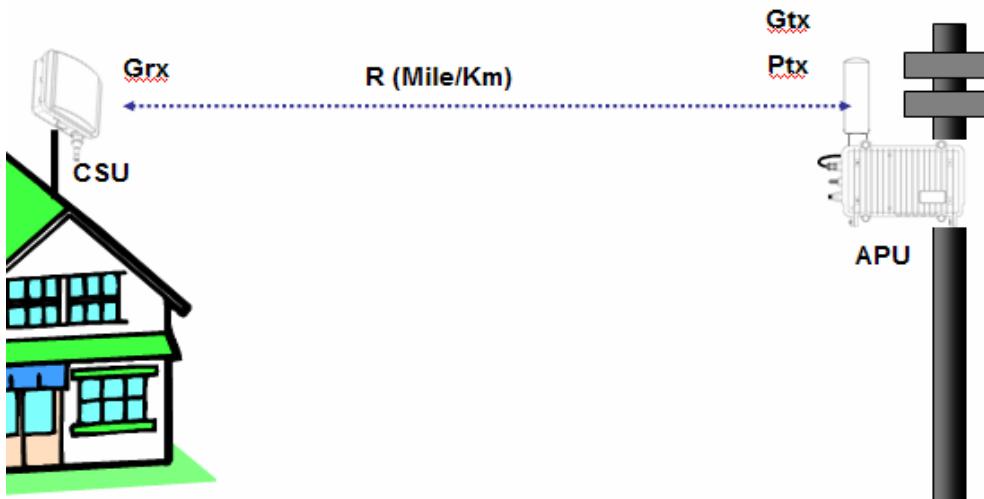

Determining the Distance between both sites

$Gs = Lt = Ptx + Gtx + Grx - (RS) = (92.4 + 20Log(F) + 20Log(R)) + 10$

$Gs = Constant = (36.6 + 20Log(F) + 20Log(R)) + 10$

Calculating Distance (R) between both sites

Case Study
Transmitter: APU, Receiver: CSU

Ptx : 15dBm
Gtx : 7dBi(Omni-directional)
Grx : 18dBi
RS : - 83dBm
F : 2.4 GHz
R: 5 mile
FM: 12 dB (Conventional Setting Value)

$Gs = Ptx + Gtx + Grx - (RS)$
$Gs(Flat Panel) = 15 + 15 + 18 - (-83) = 131$

$FSL : 36.6 + 20Log(F) + 20Log(R)$
$FSL = 36.6 + 20Log(2400) + 20Log(5) = 118.2 dB$

$Lt = FSL + FM$
$Lt = 118.2 + 12 = 130.2$

FRESNEL ZONE

For a link to truly be line-of-sight, no objects such as buildings, cars, etc. or the ground may be within a certain height perpendicular to the line of sight path called the first fresnel (pronounced fray-nell) zone.

This height of the fresnel zone H (in feet) is specified by the equation below.

$H = 43.3 \times \text{sqrt} (D/ (4xF))$

D: distance in miles between antennas
F: Frequency in GHz

Case Study

D: 10
F: 2.4

$H = 43.3 \times \text{sqrt} (10/ (4x2.4))$
$H = 44.19$ feet
$HF = 44.19 * 0.6 = 26.5$ feet

If 60 percent of the FRESNEL ZONE is free from obstructions the link will generally behave as LOS (Line of sight).

Figure A.6
FRESNEL ZONE
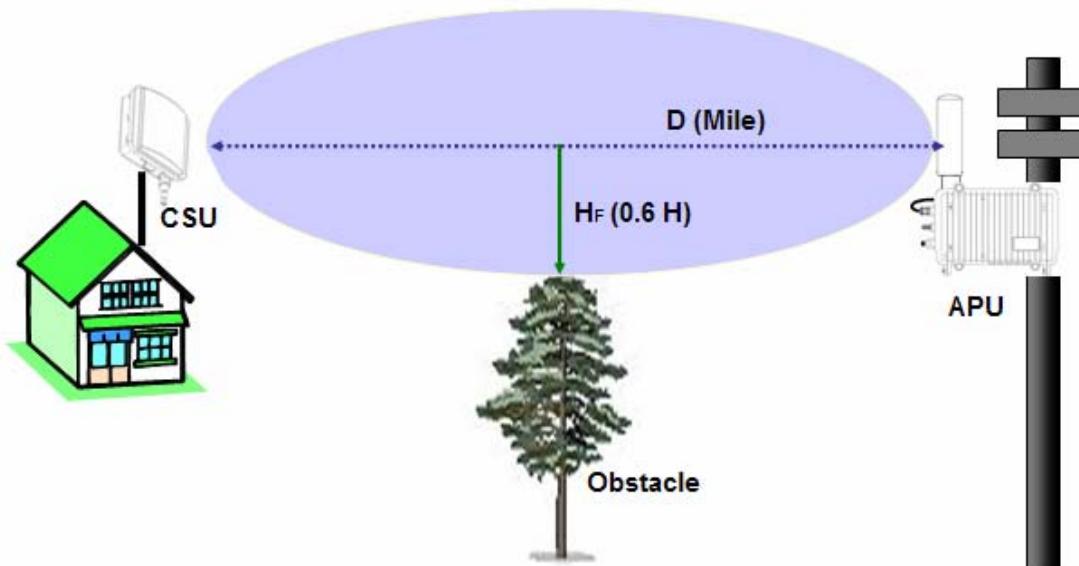

Earth bulge

For long links the curvature of the earth will may block the line of sight path unless the antennas at both ends of the link are positioned high enough above the ground. This height must be added to the FRESNEL ZONE height for each antenna.

$H_E = D^2/8$

H = Earth bulge height in feet
D=distance between antennas in miles

Case Study
D: 10 mile
$H_E = D^2/8 = 10^2/8 = 12.5$ feet

Figure A.7
Earth Bulge
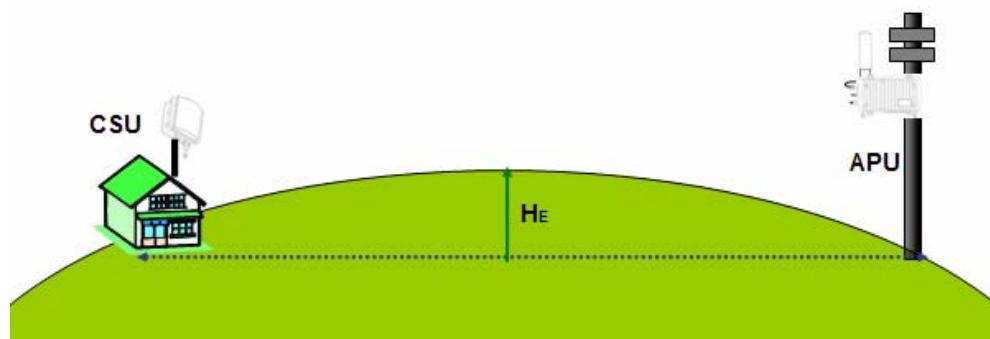

Total height required at midpoint

$H_T = H_F + H_E$

Figure A.8
Total height
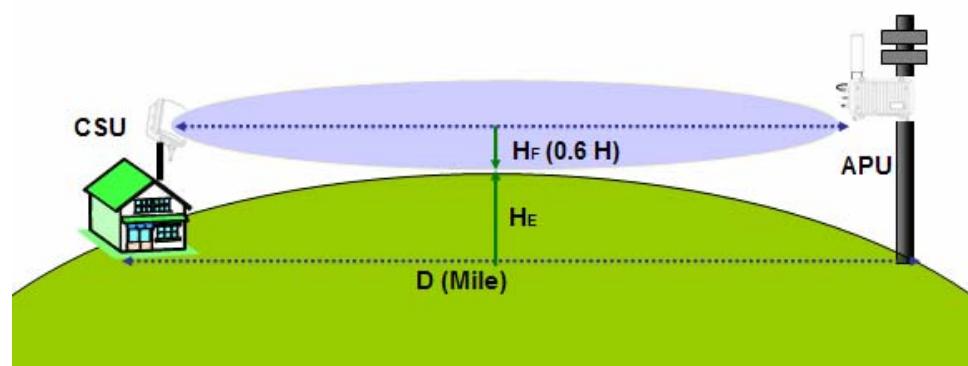

Appendix F. Wireless Network Planning

This section provides a general concept and designing tips about typical Point to Multi-Point (PMP) and Point to Point (PTP) network configuration.

Selecting Antenna Type

Directional Antenna (NTA 2407)

Flat panel antennas have a directional gain and are ideally suited for short and medium range bridging. For example, two office buildings that are across the street from one another and need to share a network connection would be a good scenario to use flat panel (directional) antennas.

Figure A.9
Directional Antenna concept (Flat Panel Antenna)
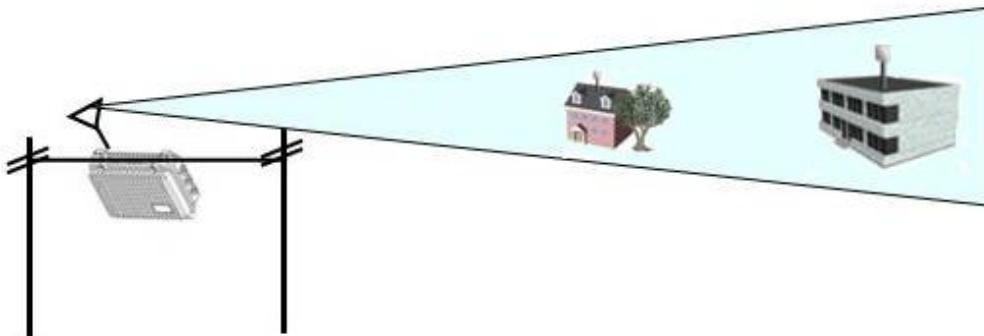

Omni-Directional Antenna (NTA 2412)

Omni-directional antennas are used when coverage in all directions around the horizontal axis of the antenna is required. Omni-directional antennas are most effective where large coverage areas are needed around a central point, they commonly used for point-to-multipoint designs with a star topology.

The antenna should be placed on top of a structure (such as a building) in the middle of the coverage area. For example, in a college campus the antenna might be placed in the centre of the campus for the greatest coverage area.

Figure A.10
Omni-directional Antenna concept
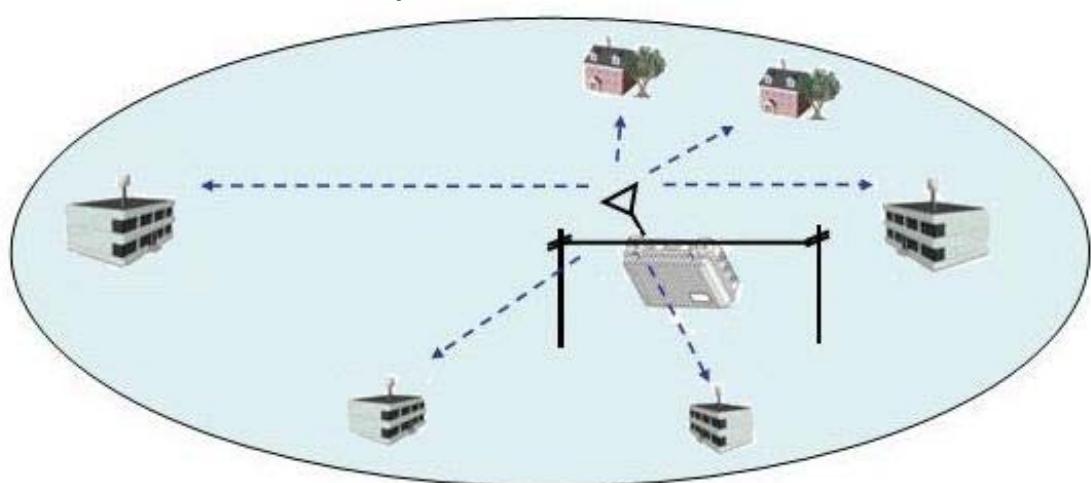

Bi-directional Antenna (NTA 2400)

Bi-directional antennas are used when coverage is required in a selected horizontal axis of the antenna is required. Bi-directional antennas are most effective where a particular coverage area is needed around a central point. For example, placing a bi-directional antenna along a street would provide coverage on each side of the street. The antenna pattern is similar to a Figure A.10 pattern.

Figure A.11
Bi-directional Antenna concept
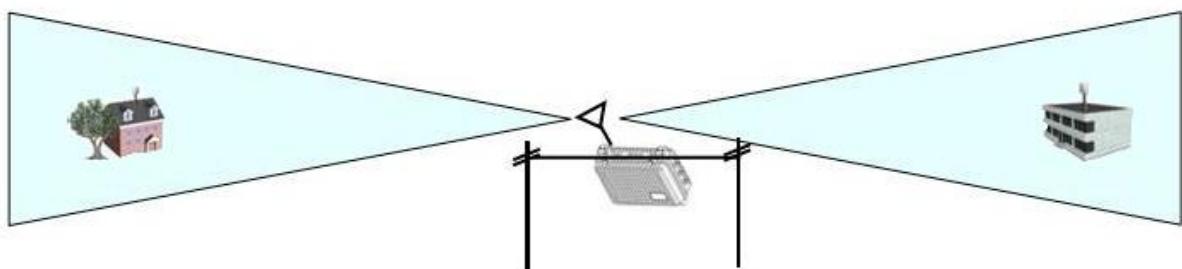

Selecting Radio Channel

Direct-Sequence Channel Layout

Most locations are deploying 802.11 products based on direct-sequence technology because the WLAN products are based on direct-sequence technologies. Direct Sequence underlies both the 2-Mbps DS PHY and the 11-Mbps HR/DSSS PHY. Both standards use identical channels and power transmission requirements.

Direct-sequence products transmit power across a 25-MHz band. Any access points must be separated by five channels to prevent inter-access point interference. Selecting frequencies for wireless LAN operation is based partly on the radio spectrum allocation where the wireless LAN is installed. See Table A.2

Table A.2
Radio channel usage in different countries

Channel number	Channel frequency (GHz)	US/Canada	ETSI[b]	France
1	2.412	•	•	
2	2.417	•	•	
3	2.422	•	•	
4	4.427	•	•	
5	2.432	•	•	
6	2.437	•	•	
7	2.442	•	•	
8	2.447	•	•	
9	2.452	•	•	
10 [c]	2.457	•	•	•
11	2.462	•	•	•
12	2.467		•	•
13	2.472		•	•

Access points can have overlapping coverage areas with full throughput, provided the radio channels differ by at least five. Only wireless LANs in the U.S., Canada, and Europe that have adopted the ETSI recommendations can operate access points with overlapping coverage areas at full throughput.

After locating the access points, make sure that any access points with overlapping coverage are separated by at least five channels. The cellular-telephone industry uses the "hex pattern" shown Figure A.11 to cover large area.

Part of the site survey is to establish the boundaries of access point coverage to prevent more than three access points from mutually overlapping, unless certain areas use multiple channels in a single area for greater throughput.

Figure A.12
Frequency planning
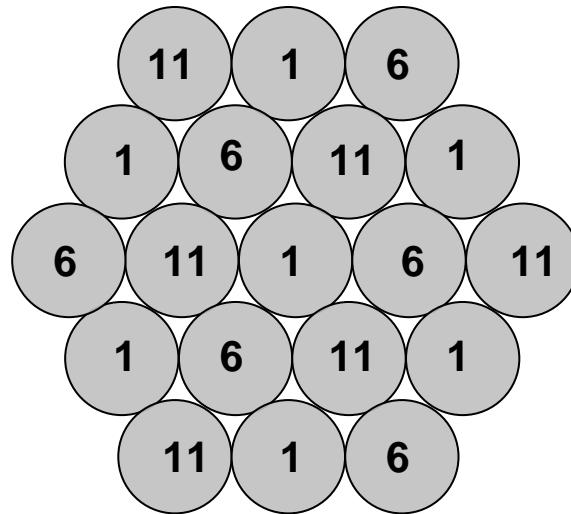

Limitations of direct-sequence channel layout

One of the problems with 802.11 direct-sequence networks and 802.11b Direct-sequence networks is that there are only three no overlapping channels. Four channels are required for no overlapping coverage in two dimensions, and more channels are required for three dimensions. When laying out frequency channels in three dimensions, always keep in mind that radio signals may penetrate the floor and ceiling.
