28:20	R/W	EIFS_TIME	EIFS time (unit: 1μs) EIFS is the defer time after reception of a CRC error packet. After deferring EIFS, the normal back-off process may proceed.	314
19:16	R/W	OFDM_XIFS_TIME	Delayed OFDM SIFS time compensator (unit: 1μs) When BB_RX_END from BBP is a delayed version the SIFS deferred will be (OFDM_SIFS_TIME - OFDM_XIFS_TIME)	4

7:0	R/W	CCK_SIFS_TIME	CCK SIFS time (unit: 1µs) Applied after CCK TX/RX.	10

Note1: EIFS = SIFS + ACK @ 1Mbps + DIFS = 10us (SIFS) + 192us (long preamble) + 14*8us (ACK) + 50us (DIFS) = 364. However, MAC should start back-off procedure after (EIFS-DIFS).

Note2: EIFS is not applied if MAC is a TXOP initiator that owns the channel.

Note3: EIFS is not started if AMPDU is only partial corrupted.

Caution: It is recommended that both (CCK_SIFS_TIME) and (OFDM_SIFS_TIME) are no less than TX/RX transition time. If the SIFS value is not long enough, a SIFS burst transmission may be replaced with a PIFS burst one.

4.5.3 Shared Memory between MCU and host (offset:0x7010~0x701F)

This register is used as the mailbox between the MCU and host driver. It's valid for RT2860 and RT2980 only.

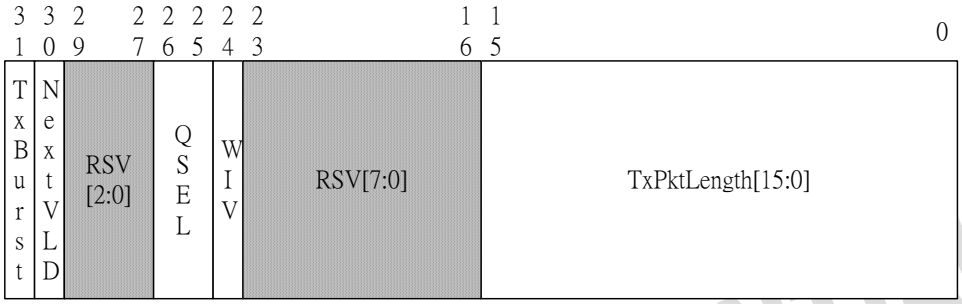
5. Descriptor and Wireless information

5.1. TXINF



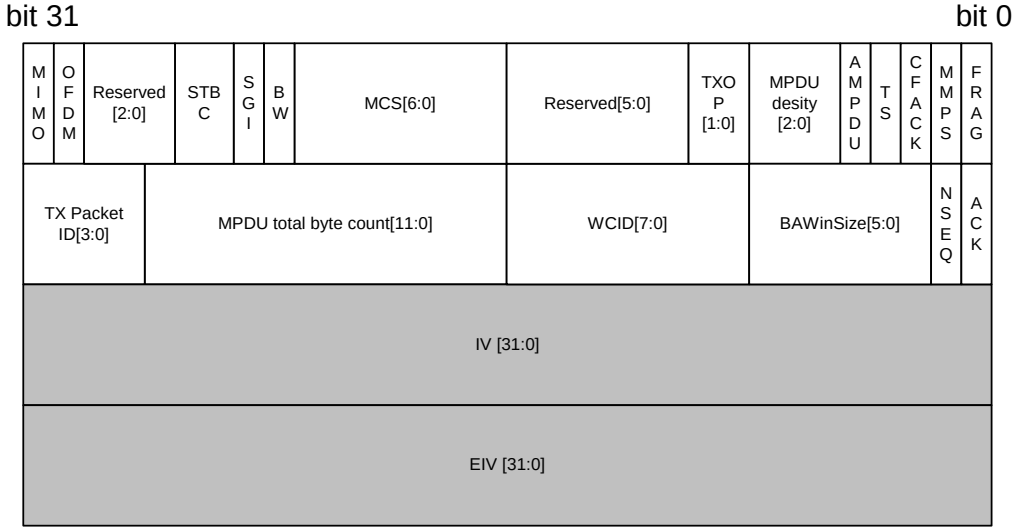
TXINF is prepared by host driver and used for passing information to USB DMA. Its size is 1 DW and put at the head of each Tx frame. Following is the detail description of each field of TXINF:

- TxBurst: force USB DMA transmit frame from current selected endpoint.
- NextVLD: host driver info USB DMA current frame is not he last frame in current Tx queue.
- QSEL[1:0]: packet buffer Q selection.

QSEL	Dest. In PBF	Function	Tx Priority
2'b00	Tx0Q	Management	Highest
2'b01	Tx1Q	HCCA	Medium
2'b10	Tx2Q	EDCA	Lowest
2'b11	N/A	N/A	N/A

- WIV: wireless information (WI) valid.
- TxPacketLength[15:0]: this field specify the frame length in unit of byte. It includes WI, 802.11 header, and payload, but TXINF is not included.

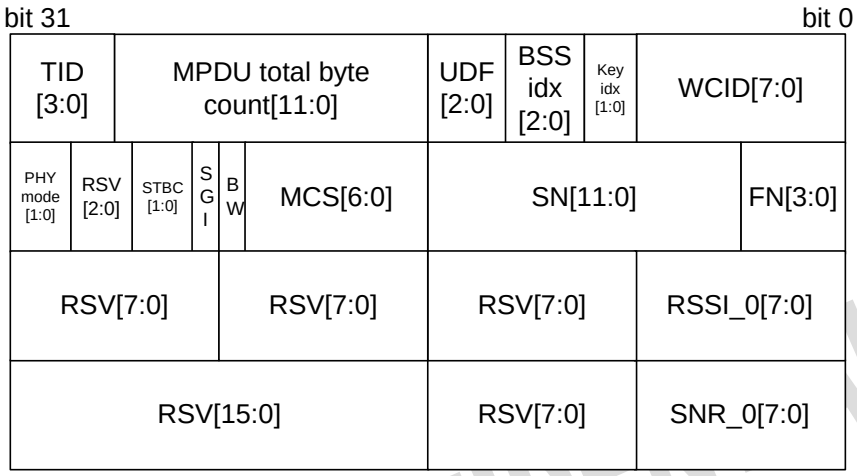
5.2. TXWI format



- FRAG: 1: to inform the TKIP engine that this is a fragment, so that the TKIP MIC is appended to the last fragment by the driver; the hardware TKIP engine only needs to insert IV/EIV and ICV.
- MMPS: 1: the remote peer is in dynamic MIMO-PS mode

- CFACK: 1: if an ACK is required by the same peer as this outgoing DATA frame, then the MAC TX will send a single DATA+CFACK frame instead of separate ACK and DATA frames. 0: no piggyback ACK is allowed for the RA of this frame.
- TS: 1: This is a BEACON or ProbeResponse frame and MAC needs to auto insert an 8-byte timestamp after the 802.11 WLAN header.
- AMPDU: This frame is eligible for AMPDU. MAC TX will aggregate subsequent outgoing frames having <same RA, same TID, AMPDU=1> whenever TXOP allows. Even if there's only one DATA frame to be sent, If the AMPDU bit in TXWI is ON, MAC will still package it as AMPDU with implicit BAR. This only adds a 4-byte AMPDU delimiter overhead to the outgoing frame and implies the response frame is a BA instead of ACK. The driver should set AMPDU=1 only after a BA session is successfully negotiated, because Block ACK is the only way to acknowledge in AMPDU case.
- MPDU density: 1/4µsec - 16µsec per-peer parameter used in outgoing A-MPDU. (This field complies with the "minimum MDPU Starting Spacing" of the A-MPDU parameter field of draft 1.08).
  000- no restriction
  001- 1/4 µsec
  010- 1/2 µsec
  011- 1 µsec
  100- 2 µsec
  101- 4 µsec
  110- 8 µsec
  111- 16 µsec
- TXOP: TX back off mode. 0: HT TXOP rule 1: PIFS TX 2: SIFS (only when previous frame exchange is successful) 3: Back off.
- "MCS/BW/ShortGI/ /OFDM/MIMO": TX data rate & MIMO parameters for this outgoing frame to be filled into BBP
- ACK: this bit informs MAC to wait for ACK or not after transmission of the frame. Even though QOD DATA frame has ACK policy in its QOS CONTROL field, MAC TX solely depends on this ACK bit to decide waiting of ACK or not.
- NSEQ: 1: to use the special h/w SEQ number register in MAC block.
- BA window size: tell MAC the maximum number of to-be-BAed frames allowed by the RA (RA's BA re-ordering buffer size)
- WCID (Wireless Client Index) : lookup result of ADDR1 in the peer table (255=not found). This index is also used to find all the attributes of the wireless peer (e.g. TX rate, TX power, pair-wise KEY, IV, EIV,). This index has consistent meaning in both driver and hardware.
- MSDU total byte count: total length of this frame.
- Packet ID: as a cookie specified by driver and will be latched into the TX result register stack. Driver use this field to identify special frame's TX result.
- IV: used by encryption engine.
- EIV: used by encryption engine.

5.3. RXWI format



- WCID: index of ADDR2 in the pair wise KEY table. This value uniquely identifies the TA. WCID=255 means not found.
- KEY Index: 0~3 extracted from IV field. For driver reference only, no particular usage so far.
- BSSID index: 0~7 for BSSID0~7. Extract from 802.11 headers (the last three bits of BSSID field).
- UDF: User Defined Field.
- MPDU total byte count: the entire MPDU length.
- TID: extracted from 802.11 QOS control field.
- FN: fragment number of the received MPDU. Extract from 802.11 headers.
- SN: sequence number of the received MPDU. Used for BA re-ordering especially that AMSDU are auto segregated by hardware and lost the 802.11 header.
- "MCS/BW/SGI/PHYmode": RX data rate & related MIMO parameters of this frame got from PLCP header. See next section for the detail.
- RSSI0: BBP reported RSSI information of the received frame.
- SNR0: BBP reported SNR information of the received frame.

5.4. Brief PHY rate format and definition

A 16-bit brief PHY rate is used in MAC hardware.

It is the same PHY rate field described in TXWI and RXWI.

13:9		Reserved
8	SGI	Short Guard Interval, only support for HT mode 0: 800ns, 1: 400ns
7	BW	Bandwidth. Support both legacy and HT modes 40Mhz in legacy mode means duplicate legacy 0: 20Mhz, 1: 40Mhz
6:0	MCS	Modulation Coding Scheme
